General Description

The monolithic MAX2451 is a quadrature demodulator with a supporting oscillator and divide-by-8 prescaler. It operates from a single +3V supply and draws only 5.5mA. The demodulator accepts an amplified and filtered IF signal in the 35MHz to 80MHz range, and demodulates it into I and Q baseband signals with 51dB of voltage conversion gain. The IF input is terminated with a 400Ω thin-film resistor for matching to an external IF filter. The baseband outputs are fully differential and have 1.2Vp-p signal swings.

Pulling the CMOS-compatible ENABLE pin low shuts down the MAX2451 and reduces the supply current to less than 2µA, typical. To minimize spurious feedback, the MAX2451’s internal oscillator is set at twice the IF frequency via external tuning components. The MAX2451 comes in a 16-pin narrow SO package.

Features

- Integrated Quadrature Phase Shifters
- On-Chip Oscillator (Requires External Tuning Circuit)
- 51dB Voltage Conversion Gain
- On-Chip Divide-by-8 Prescaler
- Baseband Output Bandwidth Up to 9MHz
- CMOS-Compatible Enable
- 5.5mA Operating Supply Current
- 2µA Shutdown Supply Current

Applications

- Digital Cordless Phones
- GSM and North American Cellular Phones
- Wireless LANs
- Digital Communications
- Pagers

Pin Configuration

ABSOLUTE MAXIMUM RATINGS
VCC, LO\_VCC to GND.........................-0.3V to +4.5V
ENABLE, TANK, TANK, I, I, Q, Q to GND.........................-0.3V to (VCC + 0.3V)
IF to GND.....................................-0.3V to +1.5V
Continuous Power Dissipation (TA = +70°C)
Narrow SO (derate 8.70mW/°C above +70°C) .............696mW
Operating Temperature Range...............................0°C to +70°C
Storage Temperature Range .........................-65°C to +165°C
Lead Temperature (soldering, 10sec) ......................+300°C

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

MAXIM
3V, Ultra-Low-Power Quadrature Demodulator

Detailed Description

The following sections describe each of the functional blocks shown in the Functional Diagram. Also refer to the Typical Application Block Diagram (Figure 1).

Demodulator

The demodulator contains a single-ended-to-differential converter, two Gilbert-cell multipliers, and two fixed gain stages. Internally, IF is terminated with a 400Ω resistor to GND. The IF input signal is AC coupled into the input amplifier, which has 14dB of gain. This amplified IF signal is fed into the I and Q channel mixers for demodulation. The multipliers mix the IF signal with the quadrature LO signals, resulting in baseband I and Q signals. The conversion gain of the multipliers is 15dB. These signals are further amplified by 21dB by the baseband amplifiers. The baseband amplifier chains are DC coupled.

Local Oscillator

The local-oscillator section is formed by an emitter-coupled differential pair. Figure 2 shows the local-oscillator equivalent circuit schematic. An external LC resonant tank determines the oscillation frequency, and the Q of this resonant tank affects the oscillator phase noise. The oscillation frequency is twice the IF frequency, for easy generation of quadrature signals.

The oscillator may be overdriven by an external source. The source should be AC coupled into TANK/TANK, and should provide 200mVp-p levels. A choke (typically 2.2µH) is required between TANK and TANK. Differential input impedance at TANK/TANK is 10kΩ. For single-ended drive, connect an AC bypass capacitor (1000pF) from TANK to GND, and AC couple TANK to the source.

The oscillator can be overdriven at frequencies up to 1GHz (500MHz IF), but conversion gain and prescaler output levels will be somewhat reduced.
**3V, Ultra-Low-Power Quadrature Demodulator**

**Quadrature Phase Generator**
The quadrature phase generator uses two latches to divide the local-oscillator frequency by two, and generates two precise quadrature signals. Internal limiting amplifiers shape the signals to approximate square waves to drive the Gilbert-cell mixers. The inphase signal (at half the local oscillator frequency) is further divided by four for the prescaler output.

**Prescaler**
The prescaler output, PRE_OUT, is buffered and swings typically 0.35Vp-p with a 10kΩ and 6pF load. It can be AC coupled to the input of a frequency synthesizer.

**Master Bias**
During normal operation, ENABLE should be above VCC - 0.4V. Pulling the ENABLE input low shuts off the master bias and reduces the circuit current to typically 2µA. The master bias section includes a bandgap reference generator and a PTAT (Proportional To Absolute Temperature) current generator.

**Applications Information**
Figure 3 shows the implementation of a resonant tank circuit. The inductor, two capacitors, and a dual varactor form the oscillator’s resonant circuit. In Figure 3, the oscillator frequency ranges from 130MHz to 160MHz. To ensure reliable start-up, the inductor is directly connected across the local oscillator’s tank ports. The two 33pF capacitors affect the Q of the resonant circuit. Other values may be chosen to meet individual application requirements. The oscillation frequency can be determined using the following formula:

\[ f_0 = \frac{1}{2\pi \sqrt{L_{EQ}C_{EQ}}} \]

where

\[ C_{EQ} = \frac{1}{\frac{1}{C_1} + \frac{1}{C_2} + \frac{2}{C_{VAR}}} + C_{STRAY} \]

and

\[ L_{EQ} = L + L_{STRAY} \]

where \( C_{STRAY} \) = parasitic capacitance and \( L_{STRAY} \) = parasitic inductance.

To alter the oscillation frequency range, change the inductance, the capacitance, or both. For best phase-noise performance, keep the Q of the resonant tank as high as possible:

\[ Q = \frac{R_{EQ}C_{EQ}}{L_{EQ}} \]

where \( R_{EQ} = 10kΩ \) (Figure 2).

The oscillation frequency can be changed by altering the control voltage, \( V_{CTRL} \).
