General Description

The MAX1540A/MAX1541 dual pulse-width modulation (PWM) controllers provide the high efficiency, excellent transient response, and high DC-output accuracy necessary for stepping down high-voltage batteries to generate low-voltage chipset and RAM power supplies in notebook computers.

The Maxim proprietary Quick-PWM™ controllers are free running, constant on-time with input feed forward. This configuration provides ultra-fast transient response, wide input-output (I/O) differential range, low supply current, and tight load-regulation characteristics. The controllers can accurately sense the inductor current across an external current-sense resistor in series with the output to ensure reliable overload and inductor saturation protection. Alternatively, the controllers can use the synchronous rectifier itself or lossless inductor current-sensing methods to provide overload protection with lower power dissipation.

Features

- Inductor-Saturation Protection
- Accurate Differential Current-Sense Inputs
- Dual Ultra-High-Efficiency Quick-PWMs with 100ns Load-Step Response
- MAX1540A
  1.8V/1.2V Fixed or 0.7V to 5.5V Adjustable Output (OUT1)
  2.5V/1.5V Fixed or 0.7V to 5.5V Adjustable Output (OUT2)
  Fixed 5V, 100mA Linear Regulator
- MAX1541
  External Reference Input (REFIN1)
  Dynamically Selectable Output Voltage—0.7V to 5.5V (OUT1)
  2.5V/1.8V Fixed or 0.7V to 5.5V Adjustable Output (OUT2)
  Optional Power-Good and Fault Blanking During Transitions
  Fixed 5V or Adjustable 100mA Linear Regulator
- 1% VOUT Accuracy over Line and Load
- 2V to 28V Battery Input Range
- 170kHz to 620kHz Selectable Switching Frequency
- Overvoltage/Undervoltage-Protection Option
- 1.7ms Digital Soft-Start
- Drives Large Synchronous-Rectifier FETs
- 2V ±0.7% Reference Output
- Separate Power-Good Window Comparators

Applications

- Notebook Computers
- Core/I/O Supplies as Low as 0.7V
- 0.7V to 5.5V Supply Rails
- CPU/Chipset/GPU with Dynamic Voltage Core Supplies (MAX1541)
- DDR Memory Termination (MAX1541)
- Active Termination Buses (MAX1541)

ABSOLUTE MAXIMUM RATINGS

V+, LDOON to GND .......................................................... 0.3V to +28V
LDOOUT to GND (MAX1540A, Note 1) .............................. 0.3V to +6V
LDOOUT to GND (MAX1541, Note 1) .............................. 0.3V to +28V
VDD to GND (MAX1541, Note 1) ........................................ 0.3V to +6V
VCC, ON_ to GND .......................................................... 0.3V to +6V
SKIP, PGOOD_ to GND .................................................. 0.3V to +6V
FB_, CSP_, ILIM_ to GND ................................................. 0.3V to +6V
TON, OVPL/UVPL, LSAT to GND ................................. 0.3V to (VCC + 0.3V)
REF, OUT_ to GND .......................................................... 0.3V to (VCC + 0.3V)
LDOIN to GND (MAX1541) ............................................... 0.3V to +28V
LDOOUT to GND (MAX1540A, Note 1) .............................. 0.3V to +6V
LDOOUT to GND (MAX1541) ............................................... 0.3V to +28V
VDD to GND (MAX1541, Note 1) ........................................ 0.3V to +6V
VCC, ON_ to GND .......................................................... 0.3V to +6V
FB1 and FB2 forced above the regulation point, LSAT = GND 0.7 1.5 mA
FB1 and FB2 forced above the regulation point, ON1 or ON2 = VCC, VLSAT > 0.5V 1.8 mA
Quiescent Supply Current (VCC) ICC ............................................ 0.7 1.5 mA
Quiescent Supply Current (V+) IVC ........................................ 1.5 25 µA
Quiescent Supply Current (LDOIN, MAX1541 Only) ILDOIN ......................... 110 µA
Standby Supply Current (VCC) ON1 = ON2 = GND, VLODOIN = V+ = 28V <1 5 µA

Note 1: For the MAX1540A, the gate-driver input supply (VDD) is internally connected to the fixed 5V linear-regulator output (LDOOUT), and the linear-regulator input supply (LDOIN) is internally connected to the battery voltage input (V+).

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

(V+ = 15V, VCC = VDD = ON1 = ON2 = 5V, SKIP = GND, LDOIN (MAX1541) = V+, T_A = 0°C to +85°C, unless otherwise noted. Typical values are at T_A = +25°C.)

**Note 1:** For the MAX1540A, the gate-driver input supply (VDD) is internally connected to the fixed 5V linear-regulator output (LDOOUT), and the linear-regulator input supply (LDOIN) is internally connected to the battery voltage input (V+).

**Note 2:** When the inductor is in continuous conduction, the output voltage has a DC regulation level higher than the error-comparator threshold by 50% of the ripple. In discontinuous conduction (SKIP = GND, light load), the output voltage has a DC regulation level higher than the trip level by approximately 1.5% due to slope compensation.

**Note 3:** On-time and off-time specifications are measured from 50% point to 50% point at the DH_ pin with LX_ = GND, VBST_ = 5V, and a 250pF capacitor connected from DH_ to LX_. Actual in-circuit times may differ due to MOSFET switching speeds.

**Note 4:** Specifications to -40°C are guaranteed by design, not production tested.

</table>
| 1 | OVP/UVP | Overvoltage/Undervoltage Protection and Discharge-Mode Control Input. This four-level logic input selects between various output fault-protection options (Table 7) by selectively enabling OVP protection and UVP protection. When enabled, the OVP limit defaults at 116% of the nominal output voltage, and the UVP limit defaults at 70% of the nominal output voltage. Discharge mode is enabled when OVP protection is also enabled. Connect OVP/UVP to the following pins for the desired function:  
  - VCC = enable OVP and discharge mode, enable UVP.  
  - Open = enable OVP and discharge mode, disable UVP.  
  - REF = disable OVP and discharge mode, enable UVP.  
  - GND = disable OVP and discharge mode, disable UVP.  
  See the **Fault Protection** and **(ON_)** sections. |
| 2 | SKIP | Pulse-Skipping Control Input. This four-level logic input enables or disables the light-load pulse-skipping operation of each output:  
  - VCC = OUT1 and OUT2 in forced-PWM mode.  
  - Open = OUT1 in forced-PWM mode, OUT2 in pulse-skipping mode.  
  - REF = OUT1 in pulse-skipping mode, OUT2 in forced-PWM mode.  
  - GND = OUT1 and OUT2 in pulse-skipping mode. |
| 3 | LSAT | Inductor-Saturation Control Input. This four-level logic input sets the inductor-current saturation limit as a multiple of the valley current-limit threshold set by ILIM, or disables the function if not required. Connect LSAT to the following pins to set the saturation current limit:  
  - VCC = 2 x ILIM(VAL)  
  - Open = 1.75 x ILIM(VAL)  
  - REF = 1.5 x ILIM(VAL)  
  - GND = disable LSAT protection  
  See the **Inductor Saturation Limit** and **Setting the Current Limit** sections. |
| 4 | TON | On-Time Selection Control Input. This four-level logic input sets the K-factor value used to determine the DH_ on-time (see the **On-Time One-Shot (TON)** section). Connect to analog ground (GND), REF, or VCC; or leave TON unconnected to select the following nominal switching frequencies:  
  - VCC = 235kHz (OUT1) / 170kHz (OUT2)  
  - Open = 345kHz (OUT1) / 255kHz (OUT2)  
  - REF = 485kHz (OUT1) / 355kHz (OUT2)  
  - GND = 620kHz (OUT1) / 460kHz (OUT2) |
| 5 | VCC | Analog Supply Input. Connect to the system supply voltage (+4.5V to +5.5V) through a series 20Ω resistor. Bypass VCC to analog ground with a 1µF or greater ceramic capacitor. |
| — | GATE | Buffered N-Channel MOSFET Gate Input. A logic low on GATE turns off the internal MOSFET so OD appears as high impedance. A logic high on GATE turns on the internal MOSFET, pulling OD to ground. |
| — | CC1 | Integrator Capacitor Connection for Controller 1. Connect a 47pF to 470pF (47pF typ) capacitor from CC1 to analog ground (GND) to set the integration time constant for the main MAX1541 controller (OUT1). |

Dual Step-Down Controllers with Saturation Protection, Dynamic Output, and Linear Regulator

Figure 1. MAX1540A Standard Application Circuit

SEE TABLE 1 FOR COMPONENT SPECIFICATIONS.

*LOWER INPUT VOLTAGES REQUIRE ADDITIONAL INPUT CAPACITANCE.
**Dual Step-Down Controllers with Saturation Protection, Dynamic Output, and Linear Regulator**

### Standard Application Circuits

The MAX1540A standard application circuit (Figure 1) generates a 1.8V and 2.5V rail for general-purpose use in a notebook computer. The MAX1541 Standard Application Circuit (Figure 12) generates a dynamically adjustable output voltage (OUT1), typical of a graphics-processor core requirement, and a fixed 2.5V output (OUT2).

See Table 1 for component selections. Table 2 lists the component manufacturers.

### Detailed Description

The MAX1540A/MAX1541 provide three independent outputs with independent enable controls. They contain two Quick-PWM step-down controllers ideal for low-voltage power supplies for notebook computers, and a 100mA linear regulator. Maxim’s proprietary Quick-PWM pulse-width modulators in the MAX1540A/ MAX1541 are specifically designed for handling fast load steps while maintaining a relatively constant operating frequency and inductor operating point over a wide range of input voltages. The Quick-PWM architecture circumvents the poor load-transient timing problems of fixed-frequency current-mode PWMs, while also avoiding the problems caused by widely varying switching frequencies in conventional constant-on-time and constant-off-time PWM schemes.

The MAX1540A linear regulator draws power from the battery voltage and generates a preset 5V, which can be used to bootstrap the buck controllers for automatic startup. The MAX1541’s linear regulator can be connected to any input source from 4.5V to 28V to generate an adjustable output voltage as low as 1.25V, or as high as the input source with 800mV of dropout at 50mA load.

Single-stage buck conversion allows the MAX1540A/ MAX1541 to directly step down high-voltage batteries for the highest possible efficiency. Alternatively, two-stage conversion (stepping down from another system supply rail instead of the battery at a higher switching frequency) allows the minimum possible physical size.

The MAX1540A generates chipset, dynamic random-access memory (DRAM), CPU I/O, or other low-voltage supplies down to 0.7V. The MAX1541 powers chipsets and graphics processor cores that require dynamically adjustable output voltages, or generates the active termination bus that must track the input reference. The MAX1540A is available in a 32-pin thin QFN package with optional inductor-saturation protection and overvoltage/undervoltage protection. The MAX1541 is available in a 40-pin thin QFN package with optional inductor-saturation protection and overvoltage/undervoltage protection.

### +5V Bias Supply (VCC and VDD)

The MAX1540A/MAX1541 require a 5V bias supply in addition to the battery. This 5V bias supply is either the MAX1540A/MAX1541s’ internal linear regulator or the notebook’s 95%-efficient 5V system supply. Keeping the bias supply external to the IC can improve efficiency and allows the fixed 5V or adjustable linear regulator (MAX1541) to be used for other applications. For the MAX1540A, the gate-driver input supply (VDD) is con-

</table>
nected internally to the fixed 5V linear-regulator output (LDOOUT). The 5V bias supply must provide VCC (PWM controller) and VDD (gate-drive power), so the maximum current drawn is:

\[ I_{B\text{IAS}} = I_{C\text{CC}} + f_{\text{SW}} (Q_{G(\text{LOW})} + Q_{G(\text{HIGH})}) \]

where \( I_{C\text{CC}} \) is 1.1mA (typ), \( f_{\text{SW}} \) is the switching frequency, and \( Q_{G(\text{LOW})} \) and \( Q_{G(\text{HIGH})} \) are the MOSFET data sheet's total gate-charge specification limits at \( V_{GS} = 5V \).

The \( V^+ \) battery input and 5V bias inputs (VCC and VDD) can be connected together if the input source is a fixed 4.5V to 5.5V supply. If the 5V bias supply powers up prior to the battery supply, the enable signals (ON1 and ON2 going from low to high) must be delayed until the battery voltage is present in order to ensure startup.

**Free-Running, Constant On-Time, PWM Controller with Input Feed Forward**

The Quick-PWM control architecture is a pseudo-fixed-frequency, constant on-time, current-mode regulator with voltage feed forward (Figure 2). This architecture relies on the output filter capacitor's ESR to act as a current-sense resistor, so the output ripple voltage provides the PWM ramp signal. The Quick-PWM algorithm is simple: the high-side switch on-time relies solely on an adjustable one-shot whose pulse width is inversely proportional to input voltage and directly proportional to output voltage. Another one-shot sets a fixed minimum off-time (400ns typ). The controller triggers the on-time one-shot when the error comparator is low, the inductor current is below the valley current-limit threshold, and the minimum off-time one-shot has timed out.

**On-Time One-Shot (TON)**

The heart of the PWM core is the one-shot that sets the high-side switch on-time. This fast, low-jitter, adjustable one-shot includes circuitry that varies the on-time in response to the battery and output voltages. The high-side switch on-time is inversely proportional to the battery voltage as measured by the \( V^+ \) input \((V_{IN} = V^+)\), and proportional to the output voltage as measured by the \( \text{OUT}_\text{IN} \) input:

\[ \text{On-Time} = K \left( \frac{V_{\text{OUT}}}{V_{\text{IN}}} \right) \]

where \( K \) (switching period) is set by the TON pin-strap connection (Table 3). This algorithm results in a nearly constant switching frequency despite the lack of a fixed-frequency clock generator. The benefits of a constant switching frequency are twofold: 1) the frequency can be selected to avoid noise-sensitive regions such as the 455kHz IF band and 2) the inductor ripple-current operating point remains relatively constant, resulting in easy design methodology and predictable output voltage ripple. The on-time for the main controller (DH1) is set 15% higher than the nominal frequency setting (200kHz, 300kHz, 420kHz, or 540kHz), while the on-time for the secondary controller (DH2) is set 15% lower than the nominal setting. This prevents audio-frequency “beating” between the two asynchronous regulators.

The on-time one-shot has good accuracy at the operating points specified in the Electrical Characteristics (approximately ±12.5% at 540kHz and 420kHz nominal settings, and ±10% with the 300kHz and 200kHz settings). On-times at operating points far removed from the conditions specified in the Electrical Characteristics can vary over a wider range.

The constant on-time translates only roughly to a constant switching frequency. The on-times guaranteed in the Electrical Characteristics are influenced by resistive losses and by switching delays in the high-side MOSFET. Resistive losses—including the inductor, both MOSFETs, and PC board copper losses in the output and ground—tend to raise the switching frequency as the load increases. The dead-time effect increases the effective on-time, reducing the switching frequency as one or both dead times add to the effective on-time. It occurs only in PWM mode \((\text{SKIP} = \text{VCC})\) and during dynamic output-voltage transitions when the inductor current reverses at light- or negative-load currents. With reversed inductor current, the inductor's EMF causes \( L\_ \) to go high earlier than normal, extending the on-time by a period equal to the driver dead time.

For loads above the critical conduction point, where the dead-time effect no longer occurs, the actual switching frequency is:

\[ f_{SW} = \frac{V_{\text{OUT}_\text{IN}} + V_{\text{DROP}1}}{\text{TON}(V_{\text{IN}} + V_{\text{DROP}1} - V_{\text{DROP}2})} \]

where \( V_{\text{DROP}1} \) is the sum of the parasitic voltage drops in the inductor discharge path, including synchronous rectifier, inductor, and PC board resistances; \( V_{\text{DROP}2} \) is the sum of the resistances in the charging path, includ-

ing the high-side switch, inductor, and PC board resistances; and $t_{ON}$ is the on-time calculated by the MAX1540A/MAX1541.

**Light-Load Operation (SKIP)**
The four-level SKIP input selects light-load, pulse-skip-
ing the high-side switch, inductor, and PC board resistances; and $t_{ON}$ is the on-time calculated by the MAX1540A/MAX1541.
(I_{OUT} < I_{LOAD(SKIP)}), the output voltage has a DC regulation level higher than the error-comparator threshold by approximately 1.5% due to slope compensation.

**Forced-PWM Mode**

The low-noise forced-PWM mode disables the zero-crossing comparator, which controls the low-side switch on-time. This forces the low-side gate-drive waveform to be constantly the complement of the high-side gate-drive waveform, so the inductor current reverses at light loads while DH maintains a duty factor of V_{OUT} / V_{IN}. The benefit of forced-PWM mode is to keep the switching frequency fairly constant. However, forced-PWM operation comes at a cost: the no-load 5V bias current remains between 4mA to 40mA, depending on the external MOSFETs and switching frequency.

Forced-PWM mode is most useful for reducing audio-frequency noise, improving load-transient response, and providing sink-current capability for dynamic output-voltage adjustment. The MAX1541 uses forced-PWM operation during all dynamic output-voltage transitions (GATE transition detected) in order to ensure fast, accurate transitions. Since forced-PWM operation disables the zero-crossing comparator, the inductor current reverses under light loads, quickly discharging the output capacitors. FBLANK determines how long the MAX1541 maintains forced-PWM operation—typically 220µs (FBLANK = VCC), 140µs (FBLANK = open or GND), or 65µs (FBLANK = REF).

**Current-Limit Protection (ILIM_)**

**Valley Current Limit**

The current-limit circuit employs a unique “valley” current-sensing algorithm that uses a current-sense resistor between CSP_ and CSN_ as the current-sensing ele-
Dual Step-Down Controllers with Saturation Protection, Dynamic Output, and Linear Regulator

In forced-PWM mode, the MAX1540A/MAX1541 also implement a negative current limit to prevent excessive reverse inductor currents when \( V_{OUT} \) is sinking current. The negative current-limit threshold is set to approximately 120% of the positive current limit and tracks the positive current limit when \( I_{LIMIT} \) is adjusted.

The current-limit threshold is adjusted with an external resistor-divider at \( I_{LIMIT} \). A 2µA to 20µA divider current is recommended for accuracy and noise immunity. The current-limit threshold adjustment range is from 25mV to 200mV. In the adjustable mode, the current-limit threshold voltage is precisely 1/10th the voltage seen at \( I_{LIMIT} \). The threshold defaults to 50mV when \( I_{LIMIT} \) is connected to \( V_{CC} \). The logic threshold for switchover to the 50mV default value is approximately \( V_{CC} - 1\text{V} \).

Carefully observe the PC board layout guidelines to ensure that noise and DC errors do not corrupt the differential current-sense signals seen by \( CSP_- \) and \( CSN_- \). Place the IC close to the sense resistor with short, direct traces, making a Kelvin-sense connection to the current-sense resistor.
**Inductor-Saturation Limit**

The LSAT connection selects an upper current-sense limit as the inductor-saturation threshold, or disables the inductor-saturation protection feature altogether (LSAT = GND). When enabled, the inductor-saturation threshold is a multiple of the positive valley current-limit threshold (Table 5) and tracks the valley current limit when ILIM is adjusted. The selected inductor-saturation threshold should give sufficient headroom above the peak inductor current so switching noise does not accidentally trip the saturation protection. Selecting an excessively high threshold may allow inductor saturation to go undetected. For an inductor with a low LIR (the ratio of the inductor ripple current to the designed maximum load current) near 20%, select the lowest saturation threshold of 1.5 x ILIM(VAL) (LSAT = REF). When using an inductor with a higher LIR, increase the inductor-saturation threshold accordingly.

When inductor-saturation protection is enabled, the MAX1540A/MAX1541 continuously monitor the inductor current through the voltage across the current-sense resistor. When the inductor-saturation threshold is exceeded, the MAX1540A/MAX1541 immediately turn off the high-side gate driver and enable a 6µA discharge current on ILIM_ (Figure 7) at the beginning of the next DH_ on-time. This reduces the voltage on ILIM_ by ΔVILIM where:

\[ ΔVILIM = \left( \frac{R_A R_B}{R_A + R_B} \right) ILIM(LSAT) \]

where the ILIM saturation fault sink current (iILIM(LSAT)) is typically 6µA (see the Electrical Characteristics table). When using the default 50mV valley current-limit threshold (ILIM_ = VCC), the ILIM_ saturation fault sink current does not lower the current-limit threshold (Figure 5).

If the inductor current remains below the saturation threshold during the next cycle, the controller disables the ILIM_ discharge current, allowing the ILIM_ voltage to return to its nominal set point. The inductor should not remain in saturation once the controller reduces the valley current limit. If the inductor remains saturated, the output voltage may drop low enough to trip the undervoltage fault protection (UVP enabled), causing the MAX1540A/MAX1541 to set the fault latch and shut down both outputs. Adding a capacitor from ILIM_ to GND slows the ILIM_ voltage change by the time constant \( τ = (R_A || R_B) \times C_{ILIM} \), where \( τ \) is between 5 to 10 switching periods. If the inductor saturation occurs only during a short load transient, the time constant allows the power supply to recover before the output voltage drops below the output undervoltage threshold.

Set \( ΔVILIM \) to be at least 30% of the ILIM_ set voltage. Calculate RA and RB using the equations below:

\[ R_A = \frac{VREF}{ILIM(LSAT)} \left( \frac{ΔVILIM}{VILIM(SET)} \right) \quad \text{with} \quad \left( \frac{ΔVILIM}{VILIM(SET)} \right) \text{set at 30%} \]

\[ R_B = \frac{R_A}{\left( \frac{VREF}{VILIM(SET)} \right) - 1} \]

Inductor-saturation sensing works best when using a current-sense resistor in series with the inductor. See the Setting the Current Limit section for various current-sense configurations (Figure 14) and LSAT recommendations.

**Dual Step-Down Controllers with Saturation Protection, Dynamic Output, and Linear Regulator**

**MOSFET Gate Drivers (DH_, DL_)**

The DH_ and DL_ drivers are optimized for driving moderate-sized high-side, and larger low-side power MOSFETs. This is consistent with the low duty factor seen in notebook applications where a large VIN - VOUT differential exists. An adaptive dead-time circuit monitors the DL_ output and prevents the high-side MOSFET from turning on until DL_ is off. A similar adaptive dead-time circuit monitors the DH_ output, preventing the low-side MOSFET from turning on until DH_ is off. There must be a low-resistance, low-inductance path from the DL_ and DH_ drivers to the MOSFET gates for the adaptive dead-time circuits to work properly; otherwise, the sense circuitry in the MAX1540A/MAX1541 interprets the MOSFET gates as "off" while charge actually remains. Use very short, wide traces (50 mils to 100 mils wide if the MOSFET is 1 in from the driver).

The internal pulldown transistor that drives DL_ low is robust, with a 0.6 Ω (typ) on-resistance. This helps prevent DL_ from being pulled up due to capacitive coupling from the drain to the gate of the low-side MOSFETs when the inductor node (LX_) quickly switches from ground to Vin. Applications with high input voltages and long inductive driver traces may require additional gate-to-source capacitance to ensure fast-rising LX_ edges do not pull up the low-side MOSFETs gate, causing shoot-through currents. The capacitive coupling between LX_ and DL_ created by the MOSFET's gate-to-drain capacitance (Crss), gate-to-source capacitance (Ciss-Crss), and additional board parasitics should not exceed the following minimum threshold:

\[
V_{GS(TH)} > V_{IN} \left( \frac{Crss}{Ciss} \right)
\]

Lot-to-lot variation of the threshold voltage can cause problems in marginal designs. Alternatively, adding a resistor less than 10Ω in series with BST_ can remedy the problem by increasing the turn-on time of the high-side MOSFET without degrading the turn-off time (Figure 8).

**POR, UVLO, and Soft-Start**

Power-on reset (POR) occurs when VCC rises above approximately 2V, resetting the fault latch and soft-start counter, powering-up the reference, and preparing the PWM for operation. Until VCC reaches 4.25V (typ), VCC undervoltage lockout (UVLO) circuitry inhibits switching. The controller inhibits switching by pulling DH_ low, and holding DL_ low when OVP and shutdown discharge are disabled or forcing DL_ high when OVP and shutdown discharge are enabled (Table 7). When VCC rises above 4.25V and ON_ is driven high, the controller activates the PWM controller and initializes soft-start.

Soft-start allows a gradual increase of the internal current-limit level during startup to reduce the input surge currents. The MAX1540A/MAX1541 divide the soft-start period into five phases. During the first phase, the controller limits the current limit to only 20% of the full current limit. If the output does not reach regulation within 425μs, soft-start enters the second phase, and the current limit is increased by another 20%. This process is repeated until the maximum current limit is reached after 1.7ms or when the output reaches the nominal regulation voltage, whichever occurs first (see the soft-start waveforms in the Typical Operating Characteristics).

**Power-Good Output (PGOOD_)**

PGOOD_ is the open-drain output for a window comparator that continuously monitors the output. PGOOD_ is actively held low in shutdown and during soft-start. After the digital soft-start terminates, PGOOD_ becomes high impedance as long as the respective output voltage is within ±10% of the nominal regulation voltage set by FB_. When the output voltage drops 10% below or rises 10% above the nominal regulation voltage, the MAX1540A/MAX1541 pull the respective power-good output (PGOOD_) low by turning on the MOSFET (Figure 9). Any fault condition forces both PGOOD1 and PGOOD2 low until the fault latch is cleared by toggling...
**Dual Step-Down Controllers with Saturation Protection, Dynamic Output, and Linear Regulator**

ON1 or ON2, or cycling VCC power below 1V. For logic-level output voltages, connect an external pullup resistor between PGOOD_ and VCC. A 100kΩ resistor works well in most applications.

Note that the power-good window detectors are completely independent of the overvoltage and undervoltage-protection fault detectors.

**Fault Blanking (MAX1541 FBLANK)**

The main MAX1541 controller (OUT1) automatically enters forced-PWM operation during all dynamic output-voltage transitions (GATE transition detected) in order to ensure fast, accurate transitions. FBLANK determines how long the main MAX1541 controller maintains forced-PWM operation (Table 6—typically 220µs (FBLANK = VCC), 140µs (FBLANK = open or GND), or 65µs (FBLANK = REF).

When fault blanking is enabled (FBLANK = VCC, open, or REF), the MAX1541 also disables the overvoltage and undervoltage fault protection for OUT1, and forces PGOOD1 to a high-impedance state during the transition period selected by FBLANK (Table 6). This prevents fault protection from latching off the MAX1541 and the PGOOD1 signal from going low when the output voltage change (ΔVOUT1) cannot occur as fast as the REFIN1 voltage change (ΔVREFIN1).

**Shutdown and Output Discharge (ON_)**

When the output discharge mode is enabled (OVP/UVP connected to VCC or left open), and either ON_ is pulled low or an OVP fault or thermal fault sets the fault latch (Table 7), the controller discharges each output through an internal 10Ω switch connected between OUT_ and ground. While the output discharges, DL_ is forced low and the PWM controller is disabled. Once the output voltage drops below 0.3V, the low-side driver pulls DL_ high, effectively clamping the output and LX_ switching node to ground. The reference remains active until both output voltages are below 0.3V to provide an accurate 0.3V discharge threshold.

When OVP/UVP is connected to REF or GND, the controller does not actively discharge either output, and the DL_ driver remains low until the system reenables the controller. Under these conditions, the output discharge rate is determined by the load current and output capacitance.

The controller detects and latches the discharge-mode state set by OVP/UVP on startup.

**Fault Protection**

The MAX1540A/MAX1541 provide over/undervoltage fault protection (Figure 9). Drive OVP/UVP to enable and disable fault protection as shown in Table 7. Once activated, the controller continuously monitors the output for undervoltage and overvoltage fault conditions.

**Overvoltage Protection (OVP)**

When the output voltage rises above 116% of the nominal regulation voltage and OVP is enabled (OVP/UVP = VCC or open), the OVP circuit sets the fault latch, shuts down both the Quick-PWM controllers, immediately pulls DH1 and DH2 low, and forces DL1 and DL2 high. This turns on the synchronous-rectifier MOSFETs with 100% duty, rapidly discharging the output capacitors and clamping both outputs to ground. Note that immediately latching DL_ high can cause the output voltages to go slightly negative due to energy stored in the output LC at the instant the OV fault occurs. If the load

cannot tolerate a negative voltage, place a power Schottky diode across the output to act as a reverse-polarity clamp. If the condition that caused the overvoltage persists (such as a shorted high-side MOSFET), the input fuse blows. The MAX1541 ignores OVP faults on OUT1 when it detects a transition on GATE (FBLANK enabled). Toggle ON1 or ON2, or cycle VCC power below 1V to clear the fault latch and restart the controller.

OVP is disabled when OVP/UVP is connected to REF or GND (Table 7).

**Undervoltage Protection (UVP)**

When the output voltage drops below 70% of the nominal regulation voltage and UVP is enabled (OVP/UVP = VCC or REF), the controller sets the fault latch and activates the output discharge sequence (see the **Shutdown and Output Discharge** section) of both outputs. When the output voltage drops to 0.3V, the driver pulls DL high so the synchronous rectifier turns on, clamping the output to GND. UVP is ignored for at least 10ms (min) after startup (ON_ rising edge), and when transitions are detected on GATE (MAX1541 only, FBLANK enabled). Toggle ON1 or ON2, or cycle VCC power below 1V to clear the fault latch and restart the controller.

UVP is disabled when OVP/UVP is left open or connected to GND (Table 7).

**Thermal Fault Protection**

The MAX1540A/MAX1541 feature a thermal fault-protection circuit. When the linear regulator is disabled (LDOON = GND), the controller sets the thermal limit at +160°C. When the linear regulator is enabled (LDOON = VCC), the controller sets the thermal limit at +150°C to protect the internal linear regulator from continuous short-circuit conditions. Once the junction temperature exceeds the thermal limit, the thermal-protection circuit activates the fault latch, pulls PGOOD1 and PGOOD2 low, disables the linear regulator, and activates the output discharge sequence of both outputs regardless of the OVP/UVP setting. Toggle ON1 or ON2, or cycle VCC power below 1V to reactivate the controller after the junction temperature cools by 10°C.

**Output Voltage**

**Preset Output Voltages**

The MAX1540A/MAX1541’s Dual Mode operation allows the selection of common voltages without requiring external components (Figure 10). For the main controller (OUT1) of the MAX1540A, connect FB1 to GND for a fixed 1.8V output, to VCC for a fixed 1.2V output, or connect FB1 directly to OUT1 for a fixed 0.7V output. For the secondary controller (OUT2) of the MAX1540A, connect FB2 to GND for a fixed 2.5V output, to VCC for a fixed 1.5V output, or connect FB2 directly to OUT2 for a fixed 0.7V output. The main controller (OUT1) of the MAX1541 regulates to the voltage set at REFIN1 (VFB1 = VREFIN1) and does not support Dual Mode operation. For the secondary controller (OUT2) of the MAX1541, connect FB2 to GND for a fixed 2.5V output, to VCC for a fixed 1.8V output, or connect FB2 directly to OUT2 for a fixed 0.7V output. Table 8 shows the output voltage configuration.

*Discharge-mode state latched on power-up.
Setting VOUT with a Resistive Voltage-Divider at FB_

The output voltage can be adjusted from 0.7V to 5.5V using a resistive voltage-divider (Figure 11). The MAX1540A regulates FB1 and FB2 to a fixed 0.7V reference voltage. The MAX1541 regulates FB1 to the voltage set at REFIN1 and regulates FB2 to a fixed 0.7V reference voltage. This makes the main MAX1541 controller (OUT1) ideal for memory applications where the termination supply must track the supply voltage. The adjusted output voltage is:

\[
V_{\text{OUT}_1} = V_{\text{FB}_1} \left(1 + \frac{R_C}{R_D}\right)
\]

where \(V_{\text{FB}_1} = 0.7\text{V}\) for the MAX1540A, and \(V_{\text{FB}_1} = \text{VREFIN1}\) and \(V_{\text{FB}_2} = 0.7\text{V}\) for the MAX1541.

Dynamic Output Voltages (MAX1541 OUT1 Only)

The MAX1541 regulates FB1 to the voltage set at REFIN1. By changing the voltage at REFIN1, the MAX1541 can be used in applications that require dynamic output-voltage changes between two set points. Figure 12 shows a dynamically adjustable resistive voltage-divider network at REFIN1. Using the GATE signal and open-drain output (OD), a resistor can be switched in and out of the REFIN1 resistor-divider, changing the voltage at REFIN1. A logic high on GATE turns on the internal N-channel MOSFET, forcing OD to a low-impedance state. A logic low on GATE disables the N-channel MOSFET, so OD is high impedance. The two output voltages (FB1 = OUT1) are determined by the following equations:

\[
V_{\text{OUT1(LOW)}} = V_{\text{REF}} \left(\frac{R_9}{R_8 + R_9}\right)
\]

\[
V_{\text{OUT1(HIGH)}} = V_{\text{REF}} \left[\frac{(R_9 + R_{10})}{R_8 + (R_9 + R_{10})}\right]
\]

The main MAX1541 controller (OUT1) automatically enters forced-PWM operation on the rising and falling edges of GATE, and remains in forced-PWM mode for a minimum time selected by FBLANK (Table 6). Forced-PWM operation is required to ensure fast, accurate negative voltage transitions when REFIN1 is lowered. Since forced-PWM operation disables the zero-crossing comparator, the inductor current may reverse under
Dual Step-Down Controllers with Saturation Protection, Dynamic Output, and Linear Regulator

light loads, quickly discharging the output capacitors. If fault blanking is enabled, the MAX1541 also disables the main controller’s (OUT1) overvoltage and undervoltage fault protection, and forces PGOOD1 to a high-impedance state for the period selected by FBLANK (Table 6).

For a step-voltage change at REFIN1, the rate of change of the output voltage is limited by the inductor current ramp, the total output capacitance, the current limit, and the load during the transition. The inductor current ramp is limited by the voltage across the inductor and the inductance. The total output capacitance determines how much current is needed to change the output voltage. Additional load current slows down the output-voltage change during a positive REFIN1 voltage change, and speeds up the output-voltage change during a negative REFIN1 voltage change. For fast positive-output-voltage transitions, the current limit must be greater than the load current plus the transition current:

\[ I_{\text{LIMIT}} > I_{\text{LOAD}} + C_{\text{OUT}} \frac{dv}{dt} \]

Adding a capacitor across REFIN1 and GND filters noise and controls the rate of change of the REFIN1 voltage during dynamic transitions. With the additional capacitance, the REFIN1 voltage slew between the two set points with a time constant given by \( R_{\text{EQ}} \times C_{\text{REFIN1}} \), where \( R_{\text{EQ}} \) is the equivalent parallel resistance seen by the slew capacitor. Looking at Figure 12, the time constant for a positive REFIN1 voltage transition is:

\[ \tau_{\text{POS}} = \frac{R_8 \times (R_9 + R_{10})}{R_8 + (R_9 + R_{10})} C_{\text{REFIN1}} \]

and the time constant for a negative REFIN1 voltage transition is:

\[ \tau_{\text{NEG}} = \frac{R_8 \times R_9}{R_8 + R_9} C_{\text{REFIN1}} \]

Linear Regulator (LDO)

The maximum input voltage for the linear regulator is 28V, while the minimum input voltage is determined by the 800mV (max) dropout voltage (\( V_{\text{LDOIN(MIN)}} = V_{\text{LDOOUT}} + V_{\text{DROPOUT}} \)) at 50mA load. Bypass the linear regulator’s output (LDOOUT) with a 4.7µF or greater capacitor, providing at least 1µF per 5mA of internal and external load on the linear regulator. The LDO can source up to 100mA for powering the controller or supplying a small external load.

For the MAX1540A, the linear regulator provides the 5V bias supply that powers the gate drivers and analog controller (Figure 1), providing stand-alone capability. The linear regulator’s input is internally connected to the battery voltage input (LDOIN = V+), and the gate-driver input supply is internally connected to the linear regulator’s output (VDD = LDOOUT). Figure 13 is the internal linear-regulator functional diagram.

For the MAX1541, the linear regulator supports Dual Mode operation to allow the selection of a 5V output voltage without requiring external components (Figure 1). Connect FBLDO to GND for a fixed 5.0V output. The linear regulator’s output voltage can be adjusted from 1.25V to 5.5V using a resistive voltage-divider (Figure 12). The MAX1541 regulates FBLDO to a 1.25V feedback voltage. The adjusted output voltage is:

\[ V_{\text{LDOOUT}} = V_{\text{FBBLDO}} \left(1 + \frac{R_{11}}{R_{12}}\right) \]

where \( V_{\text{FBBLDO}} = 1.25V \). If unused, disable the MAX1541 linear regulator by connecting LDOON to GND.
Dual Step-Down Controllers with Saturation Protection, Dynamic Output, and Linear Regulator

Figure 12. MAX1541 Standard Application Circuit

SEE TABLE 1 FOR COMPONENT SPECIFICATIONS.

*Lower input voltages require additional input capacitance.
Design Procedure

Firmly establish the input voltage range and maximum load current before choosing a switching frequency and inductor operating point (ripple-current ratio). The primary design trade-off lies in choosing a good switching frequency and inductor operating point, and the following four factors dictate the rest of the design:

- **Input voltage range:** The maximum value ($V_{IN(MAX)}$) must accommodate the worst-case, high AC-adapter voltage. The minimum value ($V_{IN(MIN)}$) must account for the lowest battery voltage after drops due to connectors, fuses, and battery selector switches. If there is a choice at all, lower input voltages result in better efficiency.

- **Maximum load current:** There are two values to consider. The peak load current ($I_{LOAD(MAX)}$) determines the instantaneous component stresses and filtering requirements and thus drives output capacitor selection, inductor saturation rating, and the design of the current-limit circuit. The continuous load current ($I_{LOAD}$) determines the thermal stresses and thus drives the selection of input capacitors, MOSFETs, and other critical heat-contributing components.

- **Switching frequency:** This choice determines the basic trade-off between size and efficiency. The optimal frequency is largely a function of maximum input voltage due to MOSFET switching losses that are proportional to frequency and $V_{IN2}$. The optimum frequency is also a moving target, due to rapid improvements in MOSFET technology that are making higher frequencies more practical.

- **Inductor operating point:** This choice provides trade-offs between size vs. efficiency and transient response vs. output ripple. Low inductor values provide better transient response and smaller physical size, but also result in lower efficiency and higher output ripple due to increased ripple currents. The minimum practical inductor value is one that causes the circuit to operate at the edge of critical conduction (where the inductor current just touches zero with every cycle at maximum load). Inductor values lower than this grant no further size-reduction benefit. The optimum operating point is usually found between 20% and 50% ripple current. When pulse skipping (SKIP low and light loads), the inductor value also determines the load-current value at which PFM/PWM switchover occurs.

**Figure 13. Internal Linear-Regulator Functional Diagram**
Inductor Selection

The switching frequency and inductor operating point determine the inductor value as follows:

\[ L = \frac{V_{OUT}(V_{IN} - V_{OUT})}{V_{IN} \times f_{SW} \times I_{LOAD(MAX)} \times LIR} \]

For example: \( I_{LOAD(MAX)} = 4A, \ V_{IN} = 12V, \ V_{OUT2} = 2.5V, \ f_{SW} = 355kHz, \ 30\% \) ripple current or \( LIR = 0.3:\)

\[ L = \frac{2.5V \times (12V - 2.5V)}{12V \times 355kHz \times 4A \times 0.3} = 4.65\mu H \]

Find a low-loss inductor with the lowest possible DC resistance that fits in the allotted dimensions. Ferrite cores are often the best choice, although powdered iron is inexpensive and can work well at 200kHz. The core must be large enough not to saturate at the peak inductor current (\( I_{PEAK}\)):

\[ I_{PEAK} = I_{LOAD(MAX)} \left( 1 + \frac{LIR}{2} \right) \]

Most inductor manufacturers provide inductors in standard values, such as 1.0\( \mu H, \ 1.5\mu H, \ 2.2\mu H, \ 3.3\mu H, \) etc. Also look for nonstandard values, which can provide a better compromise in LIR across the input voltage range. If using a swinging inductor (where the no-load inductance decreases linearly with increasing current), evaluate the LIR with properly scaled inductance values.

Transient Response

The inductor ripple current also impacts transient-response performance, especially at low \( V_{IN} - V_{OUT} \) differentials. Low inductor values allow the inductor current to slew faster, replenishing charge removed from the output filter capacitors by a sudden load step. The amount of output sag is also a function of the maximum duty factor, which can be calculated from the on-time and minimum off-time:

\[ V_{SAG} = \frac{L(\Delta I_{LOAD(MAX)})^2}{2C_{OUT} \times V_{OUT}} \left[ \left( \frac{V_{OUT} \times K}{V_{IN}} + t_{OFF(MIN)} \right)^2 \frac{(V_{IN} - V_{OUT}) \times K}{V_{IN}} \times t_{OFF(MIN)} \right] \]

where \( t_{OFF(MIN)} \) is the minimum off-time (see the Electrical Characteristics) and \( K \) is from Table 3.

The amount of overshoot during a full-load to no-load transient due to stored inductor energy can be calculated as:

\[ V_{SOAR} = \frac{(\Delta L_{LOAD(MAX)})^2}{2C_{OUT} \times V_{OUT}} \]

Setting the Current Limit

The minimum current-limit threshold must be great enough to support the maximum load current when the current limit is at the minimum tolerance value. The valley of the inductor current occurs at \( I_{LOAD(MAX)} \) minus half the ripple current; therefore:

\[ I_{LIM(VAL)} > I_{LOAD(MAX)} \left( \frac{V_{OUT}(V_{IN(MIN)} - V_{OUT})}{2V_{IN(MIN)} \times f_{SW} \times L} \right) \]

where \( I_{LIM(VAL)} \) equals the minimum valley current-limit threshold voltage divided by the current-sense resistance (\( R_{SENSE} \)). For the 50mV default setting, the minimum valley current-limit threshold is 40mV.

Connect \( I_{LIM} \) to \( VCC \) for a default 50mV valley current-limit threshold. In adjustable mode, the valley current-limit threshold is precisely 1/10th the voltage seen at \( I_{LIM} \). For an adjustable threshold, connect a resistive divider from \( REF \) to analog ground (\( GND \)) with \( I_{LIM} \) connected to the center tap. The external 250mV to 2V adjustment range corresponds to a 25mV to 200mV valley current-limit threshold. When adjusting the current limit, use 1% tolerance resistors and a divider current of approximately 10\( \mu A \) to prevent significant inaccuracy in the valley current-limit tolerance.

The current-sense method (Figure 14) and magnitude determine the achievable current-limit accuracy and power loss (Table 9). Typically, higher current-sense voltage limits provide tighter accuracy, but also dissipate more power. Most applications employ a valley current-sense voltage (\( V_{LIM(VAL)} \)) of 50mV to 100mV, so the sense resistor may be determined by:

\[ R_{SENSE} = \frac{V_{LIM(VAL)}}{I_{LIM(VAL)}} \]

For the best current-sense accuracy and overcurrent protection, use a 1% tolerance current-sense resistor between the inductor and output as shown in Figure 14a. This configuration constantly monitors the inductor current, allowing accurate valley current-limiting and inductor-saturation protection.

For low-output-voltage applications that require higher efficiency, the current-sense resistor can be connected between the source of the low-side MOSFET (\( NL_\)) and power ground (Figure 14b) with \( CSN_\) connected to the drain of \( NL_\) and \( CSP_\) connected to power ground. In this configuration, the additional current-sense resistance only dissipates power when \( NL_\) is conducting current. Inductor-saturation protection must be disabled with this configuration (\( LSAT = GND \)) since the inductor current is only properly sensed when the low-side MOSFET is turned on.
Dual Step-Down Controllers with Saturation Protection, Dynamic Output, and Linear Regulator

For high-power applications that do not require high-accuracy current sensing or inductor-saturation protection, the MAX1540A/MAX1541 can use the low-side MOSFET’s on-resistance as the current-sense element (RSENSE = RDS(ON)) by connecting CSN_ to the drain of NL_ and CSP_ to the source of NL_ (Figure 14c). Use the worst-case maximum value for RDS(ON) from the MOSFET data sheet, and add some margin for the rise in RDS(ON) with temperature. A good general rule is to allow 0.5% additional resistance for each °C of temperature rise. Inductor-saturation protection must be disabled with this configuration (LSAT = GND) since the inductor current is only properly sensed when the low-side MOSFET is turned on.

Alternatively, high-power applications that require inductor saturation can constantly detect the inductor current by connecting a series RC circuit across the inductor (Figure 14d) with an equivalent time constant:

\[
\frac{L}{R_L} = C_{EQ} \times R_{EQ}
\]

where RL is the inductor’s series DC resistance. In this configuration, the current-sense resistance is equivalent to the inductor’s DC resistance (RSENSE = RL). Use the worst-case inductance and RL values provided by the inductor manufacturer, adding some margin for the inductance drop over temperature and load.

In all cases, ensure an acceptable valley current-limit threshold voltage and inductor-saturation configurations despite inaccuracies in sense-resistance values.

Output Capacitor Selection

The output filter capacitor must have low enough equivalent series resistance (ESR) to meet output ripple and load-transient requirements, yet have high enough ESR to satisfy stability requirements.

For processor-core voltage converters and other applications where the output is subject to violent load transients, the output capacitor’s size depends on how much ESR is needed to prevent the output from dipping too low under a load transient. Ignoring the sag due to finite capacitance:

\[
R_{ESR} \leq \frac{V_{STEP}}{\Delta V_{LOAD}(\text{MAX})}
\]

In applications without large and fast load transients, the output capacitor’s size often depends on how much ESR is needed to maintain an acceptable level of output voltage ripple. The output ripple voltage of a step-down controller equals the total inductor ripple current multiplied by the output capacitor’s ESR. Therefore, the maximum ESR required to meet ripple specifications is:

\[
R_{ESR} \leq \frac{V_{RIPPLE}}{\Delta V_{LOAD}(\text{MAX}) \times LIR}
\]

The actual capacitance value required relates to the physical size needed to achieve low ESR, as well as to the chemistry of the capacitor technology. Thus, the capacitor is usually selected by ESR and voltage rating rather than by capacitance value (this is true of tantalums, OS-CONs, polymers, and other electrolytics).

When using low-capacity filter capacitors, such as ceramic capacitors, size is usually determined by the capacity needed to prevent VSAG and VSOAR from causing problems during load transients. Generally, once enough capacitance is added to meet the overshoot requirement, undershoot at the rising load edge is no longer a problem (see the VSAG and VSOAR equations in the Transient Response section). However, low-capacity filter capacitors typically have high-ESR zeros that may affect the overall stability (see the Output-Capacitor Stability Considerations section).

Dual Step-Down Controllers with Saturation Protection, Dynamic Output, and Linear Regulator

Figure 14. Current-Sense Configurations
**Output-Capacitor Stability Considerations**

For Quick-PWM controllers, stability is determined by the value of the ESR zero relative to the switching frequency. The boundary of instability is given by the following equation:

\[
\frac{1}{2\pi R_{ESR}C_{OUT}} \leq \frac{f_{SW}}{\pi}
\]

where:

\[
f_{ESR} = \frac{1}{2\pi R_{ESR}C_{OUT}}
\]

For a typical 300kHz application, the ESR zero frequency must be well below 95kHz, preferably below 50kHz. Tantalum and OS-CON capacitors in widespread use at the time of publication have typical ESR zero frequencies of 25kHz. In the design example used for inductor selection, the ESR needed to support 25mVP-P ripple is 25mV/1.2A = 20.8mΩ. One 220µF/4V Sanyo polymer (TPE) capacitor provides 15mΩ (max) ESR. This results in a zero at 48kHz, well within the bounds of stability.

Do not put high-value ceramic capacitors directly across the feedback sense point without taking precautions to ensure stability. Large ceramic capacitors can have a high-ESR zero frequency and cause erratic, unstable operation. However, it is easy to add enough series resistance by placing the capacitors a couple of inches downstream from the feedback sense point, which should be as close as possible to the inductor.

Unstable operation manifests itself in two related but distinctly different ways: double pulsing and fast-feedback loop instability. Double pulsing occurs due to noise on the output or because the ESR is so low that there is not enough voltage ramp in the output voltage signal. This “fools” the error comparator into triggering a new cycle immediately after the 400ns minimum off-time period has expired. Double pulsing is more annoying than harmful, resulting in nothing worse than increased output ripple. However, it can indicate the possible presence of loop instability due to insufficient ESR. Loop instability can result in oscillations at the output after line or load steps. Such perturbations are usually damped, but can cause the output voltage to rise above or fall below the tolerance limits.

The easiest method for checking stability is to apply a very fast zero-to-max load transient and carefully observe the output voltage ripple envelope for overshoot and ringing. It can help to monitor simultaneously the inductor current with an AC current probe. Do not allow more than one cycle of ringing after the initial step-response under/overshoot.

**Input-Capacitor Selection**

The input capacitor must meet the ripple current requirement (I_{RMS}) imposed by the switching currents:

\[
I_{RMS} = \sqrt{\sum_{X=1}^{2} P_{OUTX} V_{OUTX} (V_{IN} - V_{OUTX})} / V_{IN}
\]

For most applications, nontantalum chemistries (ceramic, aluminum, or OS-CON) are preferred due to their resistance to power-up surge currents typical of systems with a mechanical switch or connector in series with the input. If the MAX1540A/MAX1541 are operated as the second stage of a two-stage power conversion system, tantalum input capacitors are acceptable. In either configuration, choose a capacitor that has less than 10°C temperature rise at the RMS input current for optimal reliability and lifetime.

**Power MOSFET Selection**

Most of the following MOSFET guidelines focus on the challenge of obtaining high load-current capability when using high-voltage (>20V) AC adapters. Low-current applications usually require less attention.

The high-side MOSFET (\(N_H\)) must be able to dissipate the resistive losses plus the switching losses at both \(V_{IN(MIN)}\) and \(V_{IN(MAX)}\). Ideally, the losses at \(V_{IN(MIN)}\) should be roughly equal to the losses at \(V_{IN(MAX)}\), with lower losses in between. If the losses at \(V_{IN(MIN)}\) are significantly higher, consider increasing the size of \(N_H\).

Conversely, if the losses at \(V_{IN(MAX)}\) are significantly higher, consider reducing the size of \(N_H\). If \(V_{IN}\) does not vary over a wide range, maximum efficiency is achieved by selecting a high-side MOSFET (\(N_H\)) that has conduction losses equal to the switching losses.

Choose a low-side MOSFET (\(N_L\)) that has the lowest possible on-resistance (\(R_{DS(ON)}\)), comes in a moderate-sized package (i.e., 8-pin SO, DPAK, or D2PAK), and is reasonably priced. Ensure that the MAX1540A/MAX1541 DL_ gate driver can supply sufficient current to support the gate charge and the current injected into the parasitic drain-to-gate capacitor caused by the high-side MOSFET turning on; otherwise, cross-conduction problems may occur. Switching losses are not an issue for the low-side MOSFET since it is a zero-voltage switched device when used in the step-down topology.
**Power-MOSFET Dissipation**

Worst-case conduction losses occur at the duty factor extremes. For the high-side MOSFET (N\textsubscript{H}), the worst-case power dissipation due to resistance occurs at minimum input voltage:

\[
\text{PD (N\textsubscript{H} Resistance)} = \left(\frac{V_{\text{OUT}}}{V_{\text{IN}}}\right)(I_{\text{LOAD}})^2 \times R_{\text{DS(ON)}}
\]

Generally, use a small high-side MOSFET to reduce switching losses at high input voltages. However, the \(R_{\text{DS(ON)}}\) required to stay within package power-dissipation limits often restricts how small the MOSFET can be. The optimum occurs when the switching losses equal the conduction (\(R_{\text{DS(ON)}}\)) losses. High-side switching losses do not become an issue until the input is greater than approximately 15V.

Calculating the power dissipation in high-side MOSFETs (N\textsubscript{H}) due to switching losses is difficult, since it must allow for difficult-to-quantify factors that influence the turn-on and turn-off times. These factors include the internal gate resistance, gate charge, threshold voltage, source inductance, and PC board layout characteristics. The following switching loss calculation provides only a very rough estimate and is no substitute for breadboard evaluation, preferably including verification using a thermocouple mounted on N\textsubscript{H}:

\[
\text{PD (N\textsubscript{H} Switching)} = \frac{\left(\frac{V_{\text{IN(MAX)}}}{2}\right)^2 C_{\text{RSS}} \times f_{\text{SW}} \times I_{\text{LOAD}}}{I_{\text{GATE}}}
\]

where \(C_{\text{RSS}}\) is the reverse transfer capacitance of N\textsubscript{H}, and \(I_{\text{GATE}}\) is the peak gate-drive source/sink current (1A typ).

Switching losses in the high-side MOSFET can become a problem when maximum AC adapter voltages are applied due to the squared term in the switching-loss equation \((C \times V_{\text{IN}}^2 \times f_{\text{SW}})\). If the high-side MOSFET chosen for adequate \(R_{\text{DS(ON)}}\) at low-battery voltages becomes extraordinarily hot when subjected to \(V_{\text{IN(MAX)}}\), consider choosing another MOSFET with lower parasitic capacitance.

The absolute worst case for MOSFET power dissipation occurs under heavy overload conditions that are greater than \(I_{\text{LOAD(MAX)}}\) but are not high enough to exceed the current limit and cause the fault latch to trip. To protect against this possibility, “overdesign” the circuit to tolerate:

\[
I_{\text{LOAD}} = I_{\text{VALLEY(MAX)}} + \left(\frac{V_{\text{OUT}}(V_{\text{IN}} - V_{\text{OUT}})}{2V_{\text{IN}} f_{\text{SW}} L}\right)
\]

where \(I_{\text{VALLEY(MAX)}}\) is the maximum valley current allowed by the current-limit circuit, including threshold tolerance and sense-resistance variation. The MOSFETs must have a relatively large heatsink to handle the overload power dissipation.

Choose a Schottky diode (D\textsubscript{L}) with a forward-voltage drop low enough to prevent the low-side MOSFET’s body diode from turning on during the dead time. As a general rule, select a diode with a DC current rating equal to 1/3 the load current. This diode is optional and can be removed if efficiency is not critical.

---

**Applications Information**

**Step-Down Converter Dropout Performance**

The output-voltage adjustable range for continuous-conduction operation is restricted by the nonadjustable minimum off-time one-shot. For best dropout performance, use the slower (200kHz) on-time setting. When working with low input voltages, the duty-factor limit must be calculated using worst-case values for on- and off-times. Manufacturing tolerances and internal propagation delays introduce an error to the TON K-factor. This error is greater at higher frequencies (Table 3). Also, keep in mind that transient-response performance of buck regulators operated too close to dropout is poor, and bulk output capacitance must often be added (see the VSAG equation in the Design Procedure section).

The absolute point of dropout is when the inductor current ramps down during the minimum off-time \((\Delta I_{\text{DOWN}})\) as much as it ramps up during the on-time \((\Delta I_{\text{UP}})\). The ratio \(h = \Delta I_{\text{UP}}/\Delta I_{\text{DOWN}}\) indicates the controller’s ability to slew the inductor current higher in response to increased load, and must always be greater than 1. As \(h\) approaches 1, the absolute minimum dropout point, the inductor current cannot increase as much during each switching cycle, and VSAG greatly increases unless additional output capacitance is used.
A reasonable minimum value for \( h \) is 1.5, but adjusting this up or down allows trade-offs between \( V_{SAG} \), output capacitance, and minimum operating voltage. For a given value of \( h \), the minimum operating voltage can be calculated as:

\[
V_{IN(MIN)} = \frac{V_{OUT} + V_{DROP1}}{1 - \frac{h \times t_{OFF(MIN)}}{K}}
\]

where \( V_{DROP1} \) is the parasitic voltage drop in the charge path (see the On-Time One-Shot (TON) section), \( t_{OFF(MIN)} \) is from the Electrical Characteristics, and \( K \) is taken from Table 3. The absolute minimum input voltage is calculated with \( h = 1 \).

If the calculated \( V_{IN(MIN)} \) is greater than the required minimum input voltage, then operating frequency must be reduced or output capacitance added to obtain an acceptable \( V_{SAG} \). If operation near dropout is anticipated, calculate \( V_{SAG} \) to be sure of adequate transient response.

**Dropout Design Example**

- \( V_{OUT2} = 2.5V \)
- \( f_{SW} = 355kHz \)
- \( K = 3.0\mu s, \text{ worst-case } K_{MIN} = 3.3\mu s \)
- \( t_{OFF(MIN)} = 500ns \)
- \( V_{DROP1} = 100mV \)
- \( h = 1.5 \)

\[
V_{IN(MIN)} = \frac{2.5V + 0.1V}{1 - \frac{1.5 \times 500ns}{3.0\mu s}} = 3.47V
\]

Calculating again with \( h = 1 \) and the typical K-factor value (\( K = 3.3\mu s \)) gives the absolute limit of dropout:

\[
V_{IN(MIN)} = \frac{2.5V + 0.1V}{1 - \frac{1 \times 500ns}{3.3\mu s}} = 3.06V
\]

Therefore, \( V_{IN} \) must be greater than 3.06V, even with very large output capacitance, and a practical input voltage with reasonable output capacitance would be 3.47V.

**Multi-Output Voltage Settings (MAX1541 OUT1 Only)**

While the main MAX1541 controller (OUT1) is optimized to work with applications that require two dynamic output voltages, it can produce three or more output voltages if required by using discrete logic or a DAC.

Figure 15 shows an application circuit providing four voltage levels using discrete logic. Switching resistors in and out of the resistor network changes the voltage at REF1. An edge-detection circuit is added to generate a 1μs pulse on GATE to trigger the fault blanking and forced-PWM operation. When using PWM mode (\( SKIP = VCC \) or open) on the main controller, the edge-detection circuit is only required if fault blanking is enabled. Otherwise, leave OD unconnected.

**Active Bus Termination (MAX1541 OUT1 Only)**

Active-bus-termination power supplies generate a voltage rail that tracks a set reference. They are required to source and sink current. DDR memory architecture requires active bus termination. In DDR memory architecture, the termination voltage is set at exactly half the memory supply voltage. Configure the main MAX1541 controller (OUT1) to generate the termination voltage using a resistive voltage-divider at REF1. In such an application, the main MAX1541 controller (OUT1) must be kept in PWM mode (\( SKIP = VCC \) or open) in order for it to source and sink current. Figure 16 shows the main MAX1541 controller configured as a DDR termination regulator. Connect GATE and FBLANK to GND when unused.
Voltage Positioning

In applications where fast load transients occur, the output voltage changes instantly by ESR x ΔILOAD. Voltage positioning allows the use of fewer output capacitors for such applications, and maximizes the output voltage AC and DC tolerance window in tight-tolerance applications.

Figure 17 shows the connection of OUT and FB in voltage-positioned and nonvoltage-positioned circuits. In nonvoltage-positioned circuits, the MAX1540A/MAX1541 regulate at the output capacitor. In voltage-positioned circuits, the MAX1540A/MAX1541 regulate on the inductor side of the current-sense resistor. VOUT is reduced to:

\[ V_{OUT(PVS)} = V_{OUT(NO \ LOAD)} - R_{SENSE} \times I_{LOAD} \]

Figure 18 shows the voltage-positioning transient response.

PC Board Layout Guidelines

Careful PC board layout is critical to achieving low switching losses and clean, stable operation. The switching power stage requires particular attention (Figure 19). If possible, mount all the power components on the top side of the board, with their ground terminals flush against one another. Follow these guidelines for good PC board layout:

- Keep the high-current paths short, especially at the ground terminals. This practice is essential for stable, jitter-free operation.
- Keep the power traces and load connections short. This practice is essential for high efficiency. Using thick copper PC boards (2oz vs. 1oz) can enhance full-load efficiency by 1% or more. Correctly routing PC board traces is a difficult task that must be approached in terms of fractions of centimeters, where a single milliohm of excess trace resistance causes a measurable efficiency penalty.
- Minimize current-sensing errors by connecting CSP and CSN directly across the current-sense resistor (RSENSE).
- When trade-offs in trace lengths must be made, it is preferable to allow the inductor charging path to be made longer than the discharge path. For example, it is better to allow some extra distance between the input capacitors and the high-side MOSFET than to allow distance between the inductor and the low-side MOSFET or between the inductor and the output filter capacitor.
- Route high-speed switching nodes (BST, LX, DH, and DL) away from sensitive analog areas (REF, FB, CSP, CSN).

Layout Procedure

1) Place the power components first, with ground terminals adjacent (NL source, Cin, Cout, and DL anode). If possible, make all these connections on the top layer with wide, copper-filled areas.

2) Mount the controller IC adjacent to the low-side MOSFET, preferably on the back side opposite NL and NH in order to keep LX, GND, DH, and the DL gate-drive lines short and wide. The DL and DH gate traces must be short and wide (50 mils to 100 mils wide if the MOSFET is 1in from the controller IC) to keep the driver impedance low and for proper adaptive dead-time sensing.

3) Group the gate-drive components (BST diode and capacitor, VDD bypass capacitor) together near the controller IC.

4) Make the DC-DC controller ground connections as shown in Figures 1 and 12. This diagram can be viewed as having two separate ground planes: power ground, where all the high-power components go, and an analog ground plane for sensitive analog components. The analog ground plane and power ground plane must meet only at a single point directly at the IC.

5) Connect the output power planes directly to the output filter capacitor positive and negative terminals with multiple vias. Place the entire DC-DC converter circuit as close to the load as is practical.
