**MAX17681 4.5V to 42V Input, High-Efficiency, Iso-Buck DC-DC Converter**

**General Description**

The MAX17681/MAX17681A is a high-voltage, high-efficiency, iso-buck DC-DC converter designed to provide isolated power up to 5W. The device operates over a wide 4.5V to 42V input and uses primary-side feedback to regulate the output voltage.

The MAX17681/MAX17681A uses peak-current-mode control. The low-resistance, on-chip MOSFETs ensure high efficiency at full load while simplifying the PCB layout.

The MAX17681/MAX17681A devices generate a well regulated primary side voltage which is then scaled by a suitable transformer turns ratio to derive isolated secondary output rails. While both MAX17681 and MAX17681A support primary side overcurrent protection, the MAX17681A is an enhanced design that supports robust secondary-side overcurrent protection as well.

The MAX17681/MAX17681A is available in a compact 10-pin (3mm x 2mm) TDFN package. Simulation models are available.

**Applications**

- Isolated Fieldbus Interfaces
- PLC I/O Modules
- Smart Meters
- Isolated Power Supplies in Medical Equipment
- Floating Power Supply Generation

**Benefits and Features**

- Reduces External Components and Total Cost
  - No Optocoupler
  - Synchronous Primary Operation
  - All-Ceramic Capacitors, Compact Layout
- Reduces Number of DC-DC Regulators to Stock
  - Wide 4.5V to 42V Input
  - 0.9V to 0.96 x VIN Primary Output Voltage
  - Delivers Up to 5W Output Power
- Reduces Power Dissipation
  - Peak Efficiency > 90%
  - 0.9μA (typ) Shutdown Current
- Operates Reliably in Adverse Industrial Environments
  - Peak and Sink Current-Limit Protection
  - Robust Secondary-Side Output Overcurrent Protection (MAX17681A)
  - ±1.7% Feedback Accuracy
  - Programmable EN/UVLO Threshold
  - Adjustable Soft-Start
  - Overtemperature Protection
  - -40°C to +125°C Operation

**Application Circuit**

Detailed Description
The MAX17681/MAX17681A is a high-voltage, high-efficiency, iso-buck DC-DC converter designed to provide isolated power up to 5W. The device operates over a wide 4.5V to 42V input and uses primary side feedback to regulate the output voltage.

The MAX17681/MAX17681A uses peak-current-mode control. The low-resistance, on-chip MOSFETs ensure high efficiency at full load while simplifying the PCB layout. The programmable soft-start feature allows users to reduce input inrush current. The device also incorporates an output enable/undervoltage lockout pin (EN/UVLO) that allows the user to turn on the part at the desired input-voltage level. An open-drain RESET pin provides a delayed power-good signal to the system upon achieving successful regulation of the primary output voltage.

The device operates over the -40°C to +125°C industrial temperature range and is available in a compact 10-pin (3mm x 2mm) TDFN package.

Linear Regulator (VCC)
An internal linear regulator (VCC) provides a 5V nominal supply to power the internal blocks and the low-side MOSFET driver. The output of the VCC linear regulator should be bypassed with a 1μF ceramic capacitor to GND. The device employs an undervoltage-lockout circuit that disables the internal linear regulator when VCC falls below 3.7V (typ). The internal VCC linear regulator can source up to 40mA (typ) to supply the device and to power the low-side gate driver.

Enable Input (EN/UVLO) and Soft-Start (SS)
When the EN/UVLO voltage increases above 1.218V (typ), the device initiates a soft-start sequence with the duration of the soft-start being dependent on the value of the capacitor connected from SS to GND. A 5μA current source charges the capacitor and ramps up the SS pin voltage. The SS pin voltage is used as reference for the internal error amplifier. The reference ramp-up allows the output voltage to increase monotonically from zero to the target value.

The EN/UVLO can be used as an input-voltage UVLO-adjustment input. An external voltage-divider between VIN and EN/UVLO to GND adjusts the input voltage at which the device turns on or turns off. See the Setting the Input Undervoltage Lockout Level section for details. If input UVLO programming is not desired, connect the EN/UVLO to VIN (see the Electrical Characteristics table for the EN/UVLO rising- and falling-threshold voltages). Driving the EN/UVLO low disables both power MOSFETs as well as other internal circuitry and reduces VIN quiescent current to 0.9μA (typ). The SS capacitor is discharged with an internal pulldown resistor when the EN/UVLO is low. If the EN/UVLO pin is driven from an external signal source, a series resistance of minimum 1kΩ is recommended to be placed between the signal source output and the EN/UVLO pin to reduce voltage ringing on the line.

Overcurrent Protection/HICCUP Mode
The MAX17681/MAX17681A are provided with an overcurrent-protection scheme that protects the device under overload and output short-circuit conditions. A cycle-by-cycle peak current limit turns off the high-side MOSFET whenever the switch current exceeds the internal limit of 1.65A (typ). Additionally, the sink current limit turns off the low-side switch when the low side MOSFET negative current exceeds 1.25A (typ). A runaway current limit on the high-side MOSFET current at 1.7A (typ) protects the devices under high input voltage, short-circuit conditions.

The MAX17681 enters hiccup mode, either on one occurrence of the runaway current limit or when the primary output voltage (VPRI) drops to 70.5% (typ) of its nominal value after the soft-start is completed. In the MAX17681, when hiccup is triggered, the converter is protected by suspending switching for a hiccup timeout period of 32,768 clock cycles. Once the hiccup timeout period expires, soft-start is attempted again. This behaviour works well for primary output over-current events. However, when secondary-side overcurrent events occur, additional measures are required for the Iso-Buck topology to enter into hiccup mode reliably, and also support robust output voltage recovery after overcurrent removal. These measures are not supported by MAX17681.
The MAX17681A provides the robust secondary overcurrent protection, and smooth output voltage recovery after removal of overcurrent, by entering into hiccup mode after detecting 16 consecutive negative current limit events. This is supported by implementing a scheme where the primary capacitor voltage is actively discharged during the hiccup timeout period, and soft-starting both primary and secondary-side outputs.

The MAX17681A enters hiccup mode, either on one occurrence of the runaway current limit, when the primary output voltage drops to 71.14% (typ) of its nominal value after the soft-start is completed, or when 16 consecutive negative current limit events occur. When hiccup is triggered, the converter enters a hiccup timeout period of 32,768 clock cycles. During this period, the high side switch is kept off and the low side switch is turned on each cycle until the low side MOSFET negative current reaches 0.6A limit. This mode of operation effectively produces a negative current in the primary capacitor and discharges it towards zero. Once the hiccup timeout period expires, the MAX17681A smoothly soft starts both primary and secondary output voltages.

If the output capacitance is such that it is discharged to zero within one hiccup timeout period, the MAX17681A executes a normal soft-start operation upon exit from the hiccup timeout period. For cases, where the capacitor is sized such that it does not discharge to zero in one hiccup timeout period, during the next soft-start attempt the converter may re-enter the hiccup time period due to one of the event which triggers hiccup mode. Eventually the primary capacitor is completely discharged and the smooth output voltage recovery is ensured.

In summary the MAX17681 provides primary side overcurrent protection, whereas the MAX17681A provides both primary and secondary side over-current protection.

**RESET Output**

The device includes a RESET comparator to monitor the primary output voltage. The open-drain RESET output requires an external pullup resistor. RESET can sink 2mA of current while low. RESET goes high (high-impedance) 1024 switching cycles after the primary output increases above 95.5% of the nominal regulated voltage. RESET goes low when the primary output voltage drops to below 92.5% of the nominal regulated voltage. In MAX17681A, when the secondary output is shorted, the primary output voltage is discharged as well during the hiccup period. So, in this case, even for a fault on the isolated output, the RESET can be used as an indicator. RESET also goes low during thermal shutdown. RESET is valid when the device is enabled and VIN is above 4.5V.

**Thermal-Overload Protection**

Thermal-overload protection limits total power dissipation in the device. When the junction temperature of the device exceeds +165°C, an on-chip thermal sensor shuts down the device, allowing the device to cool. The thermal sensor turns the device on again after the junction temperature cools by 10°C. Carefully evaluate the total power dissipation (see the Power Dissipation section) to avoid unwanted triggering of the thermal-overload protection in normal operation.
Applications Information

Operation of the Iso-Buck Converter

The iso-buck is a synchronous-buck-converter-based topology, useful for generating isolated outputs at low power level without using an optocoupler. Figure 1 shows the basic circuit of an iso-buck converter, consists of a half-bridge transformer driver and secondary side filter.

Figure 2 shows the equivalent circuit when the high-side switch (QHS) is ON. During this time, the primary current ramps up and stores energy in the transformer magnetizing inductance $L_{PRI}$ and the primary capacitor $C_{PRI}$. The secondary side diode is reverse-biased and the load current is supplied by the secondary-side filter capacitor $C_{OUT}$.

Figure 3 shows the equivalent circuit when the low-side switch (QLS) is on. During this time, the secondary diode gets forward-biased. The primary current ramps down and releases stored energy in the transformer magnetizing inductance and the primary capacitor to the load. Operating waveforms of the converter are shown in Figure 4. Neglecting diode drop $V_D$, transformer resistances, and leakage inductance, the output voltage $V_{OUT}$ is proportional to the primary output voltage $V_{PRI}$ and is regulated by the MAX17681/MAX17681A control loop.
Primary Output Voltage Selection

Primary output voltage is regulated by the MAX17681/MAX17681A control loop. The primary output voltage can be calculated by using the equation:

\[ V_{PRI} = D_{MAX} \times V_{IN\_MIN} \]

where \( D_{MAX} \) is the maximum duty cycle of the converter and \( V_{IN\_MIN} \) is the minimum input voltage. Maximum duty cycle should be in the range of 0.4 to 0.6 for ideal iso-buck operation.

Adjusting the Primary Output Voltage

The primary output voltage is set with a resistor-divider from primary output to FB to GND (see Figure 5). Choose \( R_2 \) in the range of 10k to 49.9k and calculate \( R_1 \) using the equation:

\[ R_1 = R_2 \times \left( \frac{V_{PRI}}{0.9} - 1 \right) \]

Turns Ratio Selection

Neglecting diode drop \( V_D \), transformer resistances, and leakage inductance, the iso-buck output voltage \( V_{OUT} \) is proportional to the primary output voltage \( V_{PRI} \). The turns ratio (\( K \)) is given by the equation:

\[ \frac{N_{SEC}}{N_{PRI}} = \frac{V_{OUT} + V_D}{V_{PRI}} \]

\[ K = \frac{N_{SEC}}{N_{PRI}} \]

Turns ratio can be adjusted to match with the readily available off-the-shelf transformer turns ratio by adjusting the primary output voltage.

![Figure 5. Adjusting the Primary Output Voltage](image)

Primary Inductance Selection

Primary inductance value determines the ripple current in the transformer. The required primary inductance is given by the equation:

\[ L_{PRI} = 7 \times V_{PRI} \]

where \( L_{PRI} \) is the primary inductance in \( \mu \)H and \( V_{PRI} \) is the primary output voltage. The primary ripple current can be calculated using the equation:

\[ \Delta I = \frac{V_{PRI} \times \left( 1 - \frac{V_{PRI}}{V_{IN}} \right)}{f_{SW} \times L_{PRI}} \]

where \( L_{PRI} \) is the primary inductance in \( \mu \)H, \( f_{SW} \) is the switching frequency in Hz, \( V_{PRI} \) is the primary output voltage, \( V_{IN} \) is the input voltage.

Winding Peak and RMS Currents

Windings peak and RMS current ratings should be specified for selecting the iso-buck transformer. Primary and secondary winding peak currents are given by the equations:

\[ I_{HS\_AVG} = I_{PRI} + \sum_{i=1}^{n} I_{OUTi} \times K_i \]

\[ I_{PK\_PRI} = I_{HS\_AVG} + \frac{\Delta I}{2} \]

\[ I_{PK\_SECi} \approx \frac{I_{OUTi}}{1 - D} \]

\[ D = \frac{V_{PRI}}{V_{IN}} \]

where \( n \) is the total number of isolated outputs, \( i \) is the individual isolated output, \( I_{PRI} \) is the primary load current, \( I_{OUTi} \) is the individual secondary load current, \( K_i \) is the individual secondary turns ratio, \( D \) is the duty cycle, and \( \Delta I \) is the primary ripple current.

Primary RMS current is the sum of the high-side and low-side switch RMS currents. High-side switch RMS current:

\[ I_{HS\_RMS} = \sqrt{D \times \left( I_{HS\_AVG}^2 + \frac{\Delta I^2}{12} \right)} \]
Low-side switch RMS current:

\[ I_{LS\_RMS} = \sqrt{(1-D) \times \left( \left( I_{PK\_PRI} - \frac{1}{(1-D)} \times \sum_{i=1}^{n} (I_{OUT_i} \times K_i) \right) - \frac{\Delta I^2}{2} + \frac{\Delta I^2}{12} \right) ^2} \]

Primary winding RMS current:

\[ I_{PRI\_RMS} = \sqrt{I_{HS\_RMS}^2 + I_{LS\_RMS}^2} \]

Secondary winding RMS current is given by the equation:

\[ I_{SEC\_RMS_i} = \frac{I_{OUT_i}}{\sqrt{(1-D)}} \]

**Leakage Inductance**

Transformer leakage inductance \( L_{LEAK} \) plays a key role in determining the output voltage regulation. For better output voltage regulation, leakage inductance should be reduced to less than 1% of the primary inductance value. Higher leakage inductance also limits the amount of power delivered to the output.

**Primary Negative Peak Current**

The primary current can go negative when the low side switch is turned on. Steady-state primary negative peak current should be verified not to exceed -1A. The primary negative peak current can be calculated using the equation:

\[ I_{NEGPK\_PRI} = I_{PK\_PRI} - \left( \frac{1}{(1-D)} \times \sum_{i=1}^{n} (I_{OUT_i} \times K_i) \right) - \Delta I \]

**Specifying the Iso-Buck Transformer**

An off-the-shelf transformer or coupled inductor can be used as an Iso-buck transformer. If readily not available, use the table below to specify the Iso-buck transformer parameters to transformer vendors.

### Primary Output Capacitor Selection

X7R ceramic output capacitors are preferred due to their stability over temperature in industrial applications. The minimum required output capacitance is given by the equation:

\[ C_{PRI} = \frac{I_{HS\_AVG} \times D_{MAX}}{f_{SW} \times 0.01 \times V_{PRI}} \]

\[ D_{MAX} = \frac{V_{PRI}}{V_{IN\_MIN}} \]

Where \( I_{OUT} \) is the load current, \( K \) is the turns ratio, \( f_{SW} \) is the switching frequency, \( V_{PRI} \) is the primary output voltage, \( V_{IN\_MIN} \) is the minimum input voltage.

### Secondary Output Capacitor Selection

A secondary side capacitor supplies load current when the high-side switch is on. The required output capacitance to support 1% steady state ripple is given by the equation:

\[ C_{OUT} = \frac{I_{OUT} \times D_{MAX}}{f_{SW} \times 0.01 \times V_{OUT}} \]

It should be noted that dielectric materials used in ceramic capacitors exhibit capacitance loss due to DC bias levels and should be appropriately derated to ensure the required output capacitance is obtained in the application.

**Input Capacitor Selection**

Ceramic input capacitors are recommended for the IC. The input capacitor reduces peak current drawn from the power source and reduces noise and voltage ripple on the input caused by the switching circuitry. In applications where the source is located distant from the device input, an electrolytic capacitor should be added in parallel to the input ceramic capacitor to provide necessary damping for potential oscillations caused by the longer input power path and input ceramic capacitor. The required input capacitance can be calculated using the equation:

\[
C_{IN} = \frac{I_{HS\_AVG} \times D_{MAX} \times (1-D_{MAX})}{f_{SW} \times \Delta V_{IN}}
\]

\[
D_{MAX} = \frac{V_{PRI}}{V_{IN\_MIN}}
\]

\(\Delta V_{IN}\) is the input voltage ripple, normally 2% of the minimum input voltage, \(D_{MAX}\) is the maximum duty cycle, and \(f_{SW}\) is the switching frequency of operation.

**Secondary Diode Selection**

A secondary rectifier diode should be rated to carry peak secondary current and to withstand reverse voltage when the high-side switch is on. A Schottky diode with less forward-voltage drop should be selected for better output voltage regulation.

The peak current rating of the diode is given by:

\[
I_{PK\_DIODE} = \frac{I_{OUT}}{(1-D)}
\]

The peak reverse voltage rating of the diode is given by:

\[
V_{DIODE} = 2 \times \left( (V_{IN\_MAX} - V_{PRI}) \times K + V_{OUT} \right)
\]

Power dissipated in the diode can be calculated using the equation:

\[
P_{DIODE} = V_D \times I_{OUT}
\]

**Minimum Load Requirements**

Under light-load conditions, the iso-buck converter output voltage increases excessively due to the transformer leakage inductance and parasitic capacitance. Normally, a minimum load of 10% to 20% of the full load is sufficient to keep the converter output voltage regulation within ±5%. The output voltage regulation should be verified after testing prototype.

A resistor connected in series with a Zener diode (See R4, Z1 in Figure 9) can be used as an overvoltage protection circuit to limit the overvoltage under absolute no load conditions. The Zener diode threshold can be selected as 15% higher than the nominal regulated output voltage \(V_{OUT}\). The series resistor, \(R_1\), value can be in the range of 30Ω to 60Ω.

**Soft-Start Capacitor Selection**

The MAX17681/MAX17681A implements adjustable soft-start operation to reduce inrush current. A capacitor connected from the SS pin to GND programs the soft-start period.

The soft-start time \(t_{SS}\) is related to the capacitor connected at SS \(C_{SS}\) by the following equation:

\[
C_{SS} = 5.55 \times t_{SS}
\]

where \(t_{SS}\) is in milliseconds and \(C_{SS}\) is in nanofarads.

**Setting the Input Undervoltage Lockout Level**

The device offers an adjustable input undervoltage-lockout level. Set the voltage at which the device turns on with a resistive voltage-divider connected from \(V_{IN}\) to GND (see Figure 6). Connect the center node of the divider to EN/UVLO.

Choose \(R_1\) to be 3.3MΩ max and then calculate \(R_2\) as follows:

\[
R_2 = \frac{R_1 \times 1.218}{(V_{INU} - 1.218)}
\]

where \(V_{INU}\) is the voltage at which the device is required to turn on.
External Loop Compensation

The MAX17681/MAX17681A uses peak current-mode control scheme and needs only a simple RC network to have a stable control loop. The compensation network is shown in Figure 7. The following equations can be used for calculating the compensation components:

\[ R_{\text{COMP}} = \frac{6000 \times f_C \times \left( \frac{C_{\text{OUT}} \times (1-D)}{K^2 + C_{\text{PRI}}} \right) \times V_{\text{PRI}}}{5 \times \pi} \]

where \( R_{\text{COMP}} \) is in \( \Omega \), and the maximum limit for \( R_{\text{COMP}} \) is 12k\( \Omega \). \( f_C \) is bandwidth of the converter in Hz. Choose \( f_C \) in the range of 2kHz to 10kHz.

\[ C_{\text{COMP}} = \frac{5}{\pi \times f_C \times R_{\text{COMP}}} \]

\[ C_P = \frac{1}{2 \pi \times 50000 \times R_{\text{COMP}}} \]

Power Dissipation

Ensure that the junction temperature of the device does not exceed +125°C under the operating conditions specified for the power supply. At a particular operating condition, the power losses that lead to temperature rise of the device can be estimated as follows:

\[ P_{\text{LOSS}} = P_{\text{OUT}} \times \left( \frac{I_{\text{PRI RMS}}^2 \times R_{\text{PRI}}}{\eta} - \left| I_{\text{PRI RMS}} \right| \right) \]

\[ - \left| I_{\text{SEC RMS}}^2 \times R_{\text{SEC}} \right| \times (V_D \times I_{\text{OUT}}) \]

\[ P_{\text{OUT}} = V_{\text{OUT}} \times I_{\text{OUT}} \]

where \( P_{\text{OUT}} \) is the output power, \( \eta \) is the efficiency of power conversion, \( R_{\text{PRI}} \) is the primary resistance of the transformer, \( R_{\text{SEC}} \) is the secondary resistance of the transformer and \( V_D \) is the diode drop.

The junction temperature \( (T_J) \) of the device can be estimated at any ambient temperature \( (T_A) \) from the following equation:

\[ T_J = T_A + (\theta_{JA} \times P_{\text{LOSS}}) \]

where \( \theta_{JA} \) is the junction-to-ambient thermal impedance of the package.

PCB Layout Guidelines

Careful PCB layout is critical to achieve clean and stable operation. For a sample layout that ensures first-pass success, refer to the MAX17681/MAX17681A evaluation kit layouts available at www.maximintegrated.com. Follow these guidelines for good PCB layout:

1) All connections carrying pulsed currents must be very short and as wide as possible. The loop area of these connections must be made very small to reduce stray inductance and radiated EMI.

2) A ceramic input filter capacitor should be placed close to the VIN pin of the device. The bypass capacitor for the VCC pin should also be placed close to the VCC pin. External compensation components should be placed close to the IC and far from the LX node. The feedback trace should be routed as far as possible from the LX node.

3) Signal and power grounds must be kept separate. They should be connected together at a point where switching noise is minimum, typically the return terminal of the VCC bypass capacitor. The ground plane should be kept continuous as much as possible.

4) Multiple thermal vias that connect to a large ground plane should be provided under the exposed pad of the device, for efficient heat dissipation.

Figure 8 show the recommended component placement for the MAX17681/MAX17681A iso-buck converter.
