

Absolute Maximum Ratings

IN to PGND	-0.3V to +70V	Peak Current on NDRV	+2A
ISENSE+, ISENSE-, DIMOUT to PGND	-0.3V to +70V	Continuous Current on NDRV	+50mA
DIMOUT to ISENSE+	-8.5V to +0.3V	Continuous Power Dissipation (T _A = +70°C) (Note 1)	
ISENSE- to ISENSE+	-0.3V to +0.3V	20-pin TSSOP	
PGND to SGND	-0.6V to +0.3V	(derate 26.1mW/°C above +70°C)	2089 mW
V _{CC} , UVEN to PGND	-0.3V to +6V	20-pin TQFN	
V7V to PGND	-0.3V to +9V	(derate 25.6mW/°C above +70°C)	2051mW
BST to PGND	-0.3V to V7V + 5V	Operating Temperature Range	-40°C to +125°C
BST to NDRV	-0.3V to +6V	Junction Temperature	+150°C
NDRV to PGND	-0.3V to +7.3V	Storage Temperature Range	-65°C to +150°C
OVP, PWMDIM, ICTRL, FLT to PGND	-0.3V to +6V	Lead Temperature (soldering, 10s)	+300°C
COMP, RT, CS to PGND	-0.3V to +V _{CC}	Soldering Temperature (reflow)	+260°C
Continuous Current on IN	100mA		

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package Thermal Characteristics (Note 1)

TSSOP		TQFN	
Junction-to-Ambient Thermal Resistance (θ _{JA})	37°C/W	Junction-to-Ambient Thermal Resistance (θ _{JA})	33°C/W
Junction-to-Case Thermal Resistance (θ _{JC})	2°C/W	Junction-to-Case Thermal Resistance (θ _{JC})	2°C/W

Note 1: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

Pin Configurations

Pin Description

PIN		NAME	FUNCTION
TSSOP	TQFN		
1	17	UVEN	Undervoltage-Lockout (UVEN) Threshold/Enable Input. UVEN is a dual-function adjustable UVLO threshold input with an enable feature. Connect UVEN to V_{IN} through a resistive voltage-divider to program the UVLO threshold. Observe the absolute maximum value for this pin.
2	18	V_{CC}	5V Supply
3	19	RT	PWM Switching-Frequency Programming. Connect a resistor (R_{RT}) from RT to SGND to set the internal clock frequency. f_{OSC} (kHz) = $34200/R_{RT}$ (k Ω).
4	20	PWMDIM	Dimming-Control Input. Connect PWMDIM to an external PWM signal for PWM dimming. For analog voltage-controlled PWM dimming, connect PWMDIM to V_{CC} through a resistive voltage-divider. The dimming frequency is 200Hz under these conditions. Connect PWMDIM to SGND to turn off the LEDs.
5	1	OVP	Overshoot-Protection Input for the LED String. Connect a resistive divider between the boost output, OVP, and PGND. When the voltage on OVP exceeds 1.23V, a fast-acting comparator immediately stops PWM switching. This comparator has hysteresis of 70mV.
6	2	SGND	Signal Ground

Pin Description (continued)

PIN		NAME	FUNCTION
TSSOP	TQFN		
7	3	COMP	Compensation-Network Connection. For proper compensation, connect a suitable RC network from COMP to SGND.
8	4	$\overline{\text{FLT}}$	Active-Low, Open-Drain Fault Indicator Output. See the Fault Indicator (FLT) section.
9	5	ICTRL	Analog Dimming Control Input. Connect an analog voltage from 0 to 1.2V for analog dimming of LED current.
10	6	CS	Current-Sense Amplifier Positive Input for the Switching Regulator. Add a resistor from CS to the switching-MOSFET current-sense resistor terminal for programming the slope compensation.
11	7	PGND	Power Ground
12	8	NDRV	External n-Channel Gate-Driver Output
13	9	BST	Connect a minimum of 0.01 μF capacitor from BST to NDRV to provide power supply for the gate driver.
14	10	V7V	7V Low-Dropout Voltage-Regulator Output. Bypass V7V to PGND with a 1 μF (min) ceramic capacitor.
15, 17	12, 16	N.C	No Connection
16	11	IN	Positive Power-Supply Input. Bypass IN to PGND with at least a 1 μF ceramic capacitor.
18	13	$\overline{\text{DIMOUT}}$	External Dimming p-Channel MOSFET Gate Driver
19	14	ISENSE-	Negative LED Current-Sense Input
20	15	ISENSE+	Positive LED Current-Sense Input. The voltage between ISENSE+ and ISENSE- is proportionally regulated to the lesser of (ICTRL, 1.3V).
—	—	EP	Exposed Pad. Connect EP to a large-area contiguous copper ground plane for effective power dissipation. Do not use as the main IC ground connection. EP must be connected to GND.

Block Diagram

Detailed Description

The MAX20090 is a single-channel HB LED driver for automotive front-light applications such as high beam, low beam, daytime-running lights (DRLs), turn indicators, fog lights, and other LED lights. It can take an input voltage from 5V to 65V and drive a string of LEDs with a maximum output voltage of 65V.

The device senses output current at the high side of the LED string. High-side current sensing is required to protect for shorts from the output to the ground or battery input. It is also the most flexible scheme for driving LEDs, allowing boost, high-side buck, SEPIC mode, or buck-boost-mode configurations. The PWM input provides LED dimming ratios of up to 1000:1, and the ICTRL input provides additional analog-dimming capability in the device. The device also includes a fault flag (FLT) that indicates open string, shorted string, and thermal shut-down. The device has built-in spread-spectrum modulation for improved electromagnetic-compatibility performance. The device can also be used in zeta and Ćuk converter configurations, if necessary in some applications.

Functional Operation of the MAX20090

The operation of the device is best understood by referring to the [Block Diagram](#). The device is enabled when the UVEN pin goes above 1.24V (typ). In addition to the UVEN input, the 5V regulator and the 7V regulator inputs also need to be above their respective UVLO limits, before switching on NDRV can begin. The device is a constant-frequency, current-mode controller with a low-side nMOS gate driver. The nMOS gate-drive voltage is enhanced to 7V by the V7V pin. The control circuitry inside the device uses a 5V supply, but the gate driver has a 7V output. This can be seen from the [Block Diagram](#). When PWMDIM goes high, switching is initiated. The RT oscillator can be programmed from 200kHz to 2.2MHz by the resistor on the RT pin (R_{RT}). Additional spread-spectrum dithering is added to the oscillator to alleviate EMI problems in the LED driver. The RT oscillator is synchronized to the positive-going edge of the PWM pulse. This means that the NDRV pulse goes high at the same instant as the positive-going pulse on PWMDIM. Synchronizing the RT oscillator to the PWMDIM pulse also guarantees that the switching-frequency variation over a period of a PWMDIM pulse is the same from one PWMDIM pulse to the next. This prevents flicker during PWM dimming when spread spectrum is added to the RT oscillator.

Once PWMDIM goes high, the external switching MOSFET is turned on. A current flows through the external switching MOSFET and this current is sensed

by the voltage across the current-sense resistor from the source of the external MOSFET to PGND. The source of the external MOSFET is connected to the CS pin of the device through a slope-compensation resistor (R_{SC}) (see the [Simplified Schematic](#)). The slope-compensation current flows out of the CS pin into the R_{SC} resistor. The voltage on CS is the voltage across the current-sense resistor (R_{CS_FET}) + slope-compensation current x R_{SC}. The slope compensation prevents subharmonic oscillation when the duty cycle exceeds 50%. The current in the external inductor increases steadily when the external MOSFET is on. The voltage on CS is fed to a current-limit comparator. This current-limit comparator is used to protect the external switch from overcurrents, and causes switching to stop for that particular cycle if the CS voltage exceeds 0.418V. An offset of 1.0V is added to the CS voltage, and this voltage is fed to the positive input of a PWM comparator. The negative input of this comparator is a control voltage from the error amplifier that regulates the LED current. When the positive input of the PWM comparator exceeds the control voltage from the error amplifier, the switching is stopped for that particular cycle and the external nMOS stays off until the next switching cycle. When the external MOSFET is turned off, the inductor current decays. When the next switching cycle starts and the external MOSFET is turned on, the inductor current starts ramping back up. Through this repetitive action, the PWM-control algorithm establishes a switching duty cycle to regulate current to the LED load.

When PWMDIM goes high, the external dimming MOSFET driven by DIMOUT is also turned on. This external dimming MOSFET is a p-channel MOSFET and is connected on the high side. The source of this pMOS is connected to ISENSE- and the gate is connected to DIMOUT. The drain of this MOSFET is connected to the anode of the external LED string. In certain applications, it is not necessary to use this dimming MOSFET and in these cases, the DIMOUT pin is left open. The external pMOS is turned on when PWMDIM is high and is turned off when PWMDIM is low. During normal operation when PWMDIM is high, the voltage across the resistor from ISENSE+ to ISENSE- is regulated to a programmed voltage. This programmed voltage is $0.2 \times (V_{(CTRL)} - 0.2)$. The external pMOS switch is also used for fault protection as well. Once a fault condition is detected, the DIMOUT pin is pulled high to turn off the pMOS switch. This isolates the LED string from the fault condition and prevents excessive voltage or current from damaging the LEDs.

For operations at f_{OSC} values other than 2.2MHz, the modulation signal scales proportionally (e.g., at 400kHz, the 100 μ s modulation period increases to 190 μ s \times 2.2MHz/400kHz = 1045 μ s).

n-Channel Switching-MOSFET Driver (NDRV)

The device drives an external n-channel switching MOSFET (NDRV). NDRV swings between $V7V$ and PGND. NDRV can sink/source 2A of peak current, allowing the ICs to switch MOSFETs in high-power applications. The average current demanded from the supply to drive the external MOSFET depends on the total gate charge (Q_g) and the operating frequency of the converter (f_{SW}). Use the following equation to calculate the driver supply current (I_{NDRV}) required for the switching MOSFET:

$$I_{NDRV} = Q_g \times f_{SW}$$

Switching-MOSFET Current-Sense Input (CS)

CS is part of the current-mode-control loop. The switching control uses the voltage on CS, set by R_{CS_FET} and R_{SC} to terminate the on-pulse width of the switching cycle, thus achieving peak current-mode control. Internal leading-edge blanking of 66ns is provided to prevent premature turn-off of the switching MOSFET in each switching cycle. Resistor R_{CS_FET} is connected between the source of the n-channel switching MOSFET and PGND. During switching, a current ramp with a slope of $50\mu A \times f_{SW}$ is sourced from the CS input. This current ramp, along with resistor R_{SC} , programs the amount of slope compensation.

Overvoltage Protection (OVP)

OVP sets the overvoltage-threshold limit across the LEDs. Use a resistive divider between I_{SENSE+} to OVP and SGND to set the overvoltage-threshold limit. An internal overvoltage-protection comparator senses the differential voltage across OVP and SGND. If the differential voltage is greater than 1.23V, NDRV goes low, \overline{DIMOUT} goes high, and \overline{FLT} asserts. When the differential voltage drops by 70mV, NDRV is enabled if PWMDIM is high and \overline{DIMOUT} goes low. \overline{FLT} deasserts only if PWMDIM is high and $V_{(I_{SENSE+} - I_{SENSE-})}$ is $>$ 20mV.

Output Short-Circuit Protection

The MAX20090/MAX20090B feature output short-circuit protection. This feature is most useful when the LEDs are connected to the LED driver by long cables and there is the possibility of a short occurring when connectors are exposed.

For the MAX20090, a short circuit is detected when the following two conditions are met:

- ($V_{I_{SENSE+}} - V_{IN}$) falls below the $V_{SHORT-VOUT}$ threshold, 1.55V (typ).
- The current-sense voltage across ($V_{I_{SENSE+}} - V_{I_{SENSE-}}$) exceeds the $V_{SHORT-HIC}$ threshold, 398mV (typ).

The $V_{SHORT-VOUT}$ threshold flag in MAX20090B is disabled for applications in which ($V_{I_{SENSE+}} - V_{IN}$) is expected to be less than 1.55V (typ) during normal operation. In this case, the $V_{SHORT-HIC}$ threshold is the only criteria for detecting a short circuit.

The MAX20090/MAX20090B respond to a short circuit by entering hiccup mode, which stops NDRV and pulls \overline{DIMOUT} high to turn off the DIM FET, disconnecting the output of the LED driver from the shorted LEDs. The device waits 8192 clock cycles before attempting to drive the LEDs again.

The MAX20090AUPA has a 1 μ s deglitch filter before the hiccup mode is triggered. The MAX20090AUPB has the hiccup mode disabled.

Internal Transconductance Amplifier

The device has a built-in transconductance amplifier used to amplify the error signal inside the feedback loop. The typical transconductance is 1800 μ S. For proper operation of this transconductance amplifier, it is necessary to add a 500k Ω resistor from the COMP pin to ground. Without this resistor, the performance during PWM dimming is compromised.

Analog Dimming

The device offers an analog dimming-control input pin (ICTRL). The voltage at ICTRL sets the LED current level when $V_{ICTRL} < 1.2V$. The LED current can be linearly adjusted from zero with the voltage on ICTRL. For $V_{ICTRL} > 1.4V$, an internal reference sets the LED current. The maximum withstand voltage of this input is 6V. The LED current is guaranteed to be at zero when the ICTRL voltage is at or below 0.18V. The LED current can be linearly adjusted from zero to full scale for the ICTRL voltage in the range of 0.2V to 1.2V.

Pulsed-Dimming Input (PWMDIM)

PWMDIM functions with either analog or PWM control signals. Once the internal pulse detector detects three successive edges of a PWM signal with a frequency between 60Hz and 2kHz, the device synchronizes to the external signal and pulse-width modulates the LED current at the external PWMDIM input frequency, with the same duty cycle as the PWMDIM input. If an analog control signal is applied to PWMDIM, the device compares the DC input to an internally generated 200Hz

The LED current can also be programmed adjusting the voltage on ICTRL when $V_{ICTRL} \leq 1.2V$ (analog dimming). The current is given by:

$$I_{LED} = (V_{ICTRL} - 0.2)/(5 \times R_{CS_LED})$$

Programming the Switching Frequency

The internal oscillator of the device is programmable from 200kHz to 2.2MHz using a single resistor at RT.

Use the following equation to calculate the value of the resistor (RRT):

$$R_{RT}(k\Omega) = 34,200/f_{OSC}(kHz)$$

where $f_{OSC}(kHz)$ is the desired switching frequency in kHz.

The frequency calculated from the above formula may not be totally accurate, and some final trimming might be needed. The resistor values for a frequency of 200kHz is 88k Ω , 1MHz is 34.2k Ω , and 2.2MHz is 14.7k Ω .

Additional $\pm 6\%$ spread spectrum is added internally to the oscillator to improve EMI performance.

Setting the Overvoltage Threshold

The overvoltage threshold is set by resistors R_{OVP1} and R_{OVP2} (see the [Simplified Schematic](#)). The overvoltage circuit in the device is activated when the voltage on OVP with respect to GND exceeds 1.23V. Use the following equation to set the desired overvoltage threshold:

$$V_{OVP} = 1.23 \times (R_{OVP1} + R_{OVP2})/R_{OVP2}$$

Inductor Selection

Boost Configuration

In the boost converter, the average inductor current varies with the line voltage. The maximum average current occurs at the lowest line voltage.

For the boost converter, the average inductor current is equal to the input current. Calculate maximum duty cycle using the equation below:

$$D_{MAX} = (V_{LED} - V_D - V_{INMIN})/(V_{LED} + V_D - V_{FET})$$

where V_{LED} is the forward voltage of the LED string in volts, V_D is the forward drop of rectifier diode D1 in volts (approximately 0.6V), V_{INMIN} is the minimum input supply voltage in volts, and V_{FET} is the average drain-to source voltage of MOSFET N1 in volts when it is on. Use an approximate value of 0.2V initially to calculate D_{MAX} . A more accurate value of the maximum duty cycle can be calculated once the power MOSFET is selected based on the maximum inductor current. Use the following equations to calculate the maximum average inductor

current (I_{LAVG}), peak-to-peak inductor current ripple (ΔI_L), and the peak inductor current (I_{LP}) in amperes:

$$I_{LAVG} = I_{LED}/(1 - D_{MAX})$$

Allowing the peak-to-peak inductor ripple to be ΔI_L , the peak inductor current is given by:

$$I_{LP} = I_{LAVG} + 0.5 \times \Delta I_L$$

The inductance value (L) of inductor L1 in henries (H) is calculated as:

$$L = (V_{INMIN} - V_{FET}) \times D_{MAX}/(f_{SW} \times \Delta I_L)$$

where f_{SW} is the switching frequency in hertz, V_{INMIN} and V_{FET} are in volts, and ΔI_L is in amperes. Choose an inductor that has a minimum inductance greater than the calculated value. The current rating of the inductor should be higher than I_{LP} at the operating temperature.

Buck-Boost Configuration

In the buck-boost LED driver, the average inductor current is equal to the input current plus the LED current. Calculate the maximum duty cycle using the following equation:

$$D_{MAX} = (V_{LED} + V_D)/(V_{LED} + V_D + V_{INMIN} - V_{FET})$$

where V_{LED} is the forward voltage of the LED string in volts, V_D is the forward drop of rectifier diode D1 (~0.6V) in volts, V_{INMIN} is the minimum input supply voltage in volts, and V_{FET} is the average drain-to-source voltage of MOSFET N1 in volts when it is on. Use an approximate value of 0.2V initially to calculate D_{MAX} . A more accurate value of the maximum duty cycle can be calculated once the power MOSFET is selected based on the maximum inductor current.

Use the equations below to calculate the maximum average inductor current (I_{LAVG}), peak-to-peak inductor current ripple (ΔI_L), and the peak inductor current (I_{LP}) in amperes:

$$I_{LAVG} = I_{LED}/(1 - D_{MAX})$$

Allowing the peak-to-peak inductor ripple to be ΔI_L :

$$I_{LP} = I_{LAVG} + 0.5 \times \Delta I_L$$

where I_{LP} is the peak inductor current.

The inductance value (L) of inductor L1 in henries is calculated as:

$$L = (V_{INMIN} - V_{FET}) \times D_{MAX}/(f_{SW} \times \Delta I_L)$$

where f_{SW} is the switching frequency in hertz, V_{INMIN} and V_{FET} are in volts, and ΔI_L is in amperes. Choose an inductor that has a minimum inductance greater than the calculated value.

The minimum value of the peak current-limit comparator is 0.388V. The current-sense resistor value is given by:

$$R_{CS_FET} = (0.388 - \text{slope compensation voltage}) / I_{LP}$$

where I_{LP} is the peak inductor current that occurs at low line in the boost, SEPIC, and buck-boost configuration.

For boost configuration:

$$R_{CS_FET} = \frac{0.388}{\left(I_{LP} + 0.75 D_{MAX} \frac{V_{LED} - 2V_{INMIN}}{L_{MIN} f_{SW}} \right)}$$

For buck-boost configuration:

$$R_{CS_FET} = \frac{0.388}{\left(I_{LP} + 0.75 D_{MAX} \frac{V_{LED} - V_{INMIN}}{L_{MIN} f_{SW}} \right)}$$

For SEPIC configuration:

$$R_{CS_FET} = \frac{0.388}{\left(I_{LP1} + I_{LP2} + 0.75 D_{MAX} \frac{V_{LED} - V_{INMIN}}{f_{SW} \sqrt{L_{1MIN} L_{2MIN}}} \right)}$$

Input Capacitor

The input-filter capacitor bypasses the ripple current drawn by the converter and reduces the amplitude of high-frequency current conducted to the input supply.

The ESR, ESL, and bulk capacitance of the input capacitor contribute to the input ripple. Use a low-ESR input capacitor that can handle the maximum input RMS ripple current from the converter. For the boost configuration, the input current is the same as the inductor current. For buck-boost configuration, the input current is the inductor current minus the LED current. However, for both configurations, the ripple current that the input filter capacitor has to supply is the same as the inductor ripple current with the condition that the output filter capacitor should be connected to ground for buck-boost configuration. Neglecting the effect of LED current ripple, the calculation of the input capacitor for boost, as well as buck-boost configurations is the same. Neglecting the effect of the ESL, ESR, and bulk capacitance at the input contributes to the input-voltage ripple. For simplicity, assume that the contribution from the ESR and the bulk capacitance is equal. This allows 50% of the ripple for the bulk capacitance. The capacitance is given by:

$$C_{IN} > \Delta I_L / (4 \times \Delta V_{IN} \times f_{SW})$$

where ΔI_L is in amperes, C_{IN} is in farads, f_{SW} is in hertz, and ΔV_{IN} is in volts. The remaining 50% of allowable ripple is for the ESR of the output capacitor.

Use X7R ceramic capacitors for optimal performance. The selected capacitor should have the minimum required capacitance at the operating voltage.

www.maximintegrated.com

In the buck mode, the input capacitor has large pulsed currents due to the current flowing in the freewheeling diode when the switching MOSFET is off. It is very important to consider the ripple-current rating of the input capacitor in this application.

Output Capacitor Selection

The function of the output capacitor is to reduce the output ripple to acceptable levels. The ESR, ESL, and bulk capacitance of the output capacitor contribute to the output ripple. In most applications, the output ESR and ESL effects can be dramatically reduced by using low-ESR ceramic capacitors. To reduce the ESL and ESR effects, connect multiple ceramic capacitors in parallel to achieve the required bulk capacitance. To minimize audible noise generated by the ceramic capacitors during PWM dimming, it may be necessary to minimize the number of ceramic capacitors on the output. In these cases, an additional electrolytic or tantalum capacitor provides most of the bulk capacitance.

Boost and Buck-Boost Configurations

The calculation of the output capacitance is the same for both boost and buck-boost configurations. The output ripple is caused by the ESR and bulk capacitance of the output capacitor if the ESL effect is considered negligible. For simplicity, assume that the contributions from ESR and bulk capacitance are equal, allowing 50% of the ripple for the bulk capacitance. The capacitance is given by:

$$C_{OUT} \geq \frac{I_{LED} \times 2 \times D_{MAX}}{V_{OUTRIPPLE} \times f_{SW}}$$

where I_{LED} is in amperes, C_{OUT} is in farads, f_{SW} is in hertz, and $V_{OUTRIPPLE}$ is in volts. The remaining 50% of allowable ripple is for the ESR of the output capacitor. Based on this, the ESR of the output capacitor is given by:

$$ESR_{COUT} < \frac{V_{OUTRIPPLE} (\Omega)}{(I_{LP} \times 2)}$$

where I_{LP} is the peak inductor current in amperes.

Rectifier Diode Selection

Use a Schottky diode as the rectifier (D1) for fast switching and to reduce power dissipation. The selected Schottky diode must have a voltage rating 20% above the maximum converter output voltage. The maximum converter output voltage is V_{LED} in the boost configuration and $V_{LED} + V_{INMAX}$ in the buck-boost configuration.

The current rating of the diode should be greater than I_D in the following equation:

$$I_D = I_{LAVG} (1 - D_{MAX}) 1.5$$

where I_{LAVG} is the average inductor current.

Switching MOSFET Selection

The switching MOSFET (N1) should have a voltage rating sufficient to withstand the maximum output voltage together with the diode drop of rectifier diode D1, and any possible overshoot due to ringing caused by parasitic inductances and capacitances. Use a MOSFET with a drain-to-source voltage rating higher than that calculated by the following equations:

Boost configuration:

$$V_{DS} = (V_{LED} + V_D) \times 1.2$$

Buck-boost configuration:

$$V_{DS} = (V_{LED} + V_{INMAX} + V_D) \times 1.2$$

where V_{LED} is the LED string voltage, V_{INMAX} is the maximum input voltage, and V_D is the forward drop of the rectifier diode. The factor 1.2 provides 20% safety margin.

Dimming MOSFET Selection

Select a dimming MOSFET (P1) with continuous current rating at the operating temperature higher than the LED current by 30%. The drain-to-source voltage rating of the dimming MOSFET must be higher than V_{LED} by 20%.

Dimming MOSFET Slew Rate Control

Filter capacitors placed on the drain side (LED side) of the P1 pMOS dimming FET may cause a current spike from the output capacitor when the dimming FET turns on. If the current spike is large enough, it may trigger the short-circuit protection of the MAX20090/MAX20090B. To reduce these current spike amplitudes, the turn-on slew rate of the dimming FET can be reduced. Slew-rate control of the P1 dimming MOSFET may be achieved by adding a resistor R_G in series with the gate, and a capacitor C_G across the gate and drain.

Choose $R_G = 10k\Omega$ and C_G according to the following equation:

$$C_G = (C_{LED} \times R_{CS_LED} \times (7V - V_{THDIM}) / (0.25 \times V_{CS_LIMIT} \times R_G)$$

Where C_{LED} = Total capacitance (capacitance across LEDs + EMI filter capacitance) on the drain side of the dimming FET

R_{CS_LED} = LED current-sense resistor

V_{THDIM} = Threshold voltage of the DIMFET pMOS

V_{CS_LIMIT} = Current-limit threshold

The diode DR should be added across R_G to enable fast turn-off of the DIMFET during LED short-fault conditions. Because the ISENSE+ sensing input is also the supply rail for the DIMOUT driver, any high-impedance component (such as a Ferrite Bead) in series with the ISENSE+ input is not recommended. For a typical application, $R_G = 10k\Omega$ and $C_G = 1nF$ is sufficient. See [Figure 1](#).

Feedback Compensation

The LED current-control loop comprising the switching converter, LED current amplifier, and the error amplifier should be compensated for stable control of the LED current. The switching converter small-signal transfer function has a right half-plane (RHP) zero for both boost and buck-boost configurations, as the inductor current is in continuous-conduction mode. The RHP zero adds a 20dB/decade gain together with a 90° phase lag, which is difficult to compensate. The easiest way to avoid this zero is to roll off the loop gain to 0dB at a frequency less than 1/5 of the RHP zero frequency with a -20dB/decade slope.

The worst-case RHP zero frequency (f_{ZRHP}) is calculated as follows:

Boost configuration:

$$f_{ZRHP} = \frac{V_{LED} \times (1 - D_{MAX})^2}{2\pi \times L \times I_{LED}}$$

Buck-boost configuration:

$$f_{ZRHP} = \frac{V_{LED} \times (1 - D_{MAX})^2}{2\pi \times L \times I_{LED}}$$

where f_{ZRHP} is in hertz, V_{LED} is in volts, L is the inductance value of $L1$ in henries (H), and I_{LED} is in amperes.

The switching converter small-signal transfer function also has an output pole for both boost and buck-boost configurations. The effective output impedance that determines the output pole frequency together with the output filter capacitance is calculated as:

Boost configuration:

$$R_{OUT} = \frac{(R_{LED} + R_{CS_LED}) \times V_{LED}}{(R_{LED} + R_{CS_LED}) \times I_{LED} + V_{LED}}$$

Ordering Information

PART	DESCRIPTION	PIN-PACKAGE
MAX20090ATP/V+	No filter before hiccup mode	20 TQFN-EP*
MAX20090ATP/VY+	No filter before hiccup mode	20 TQFN-EP (SW)*
MAX20090AUP/V+	No filter before hiccup mode	20 TSSOP-EP*
MAX20090AUPA/V+	1 μ s filter before hiccup mode	20 TSSOP-EP*
MAX20090AUPB/V+	No hiccup mode	20 TSSOP-EP*
MAX20090BATP/V+	No filter before hiccup mode/SEPIC configuration applications	20 TQFN-EP*
MAX20090BATP/VY+	No filter before hiccup mode/SEPIC configuration applications	20 TQFN-EP (SW)*
MAX20090BAUP/V+	No filter before hiccup mode/SEPIC configuration applications	20 TSSOP-EP*

Note: All parts operate over the -40°C to +125°C automotive temperature range.

V denotes an automotive-qualified part.

+Denotes a lead(Pb)-free/RoHS-compliant package.

*EP = Exposed pad.

(SW) = Side wettable.

Chip Information

PROCESS: BiCMOS

Package Information

For the latest package outline information and land patterns (footprints), go to www.maximintegrated.com/packages. Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

PACKAGE TYPE	PACKAGE CODE	OUTLINE NO.	LAND PATTERN NO.
20 TQFN-EP	T2044+4C	21-100172	90-0409
20 TQFN-EP (SW)	T2044Y+4C	21-100068	90-0409
20 TSSOP-EP	U20E+3C	21-100132	90-100049

Revision History

REVISION NUMBER	REVISION DATE	DESCRIPTION	PAGES CHANGED
0	2/17	Initial release	—
1	6/17	Changed data sheet title and deleted tape-and-reel variants from <i>Ordering Information</i>	1–29
2	7/17	Removed future product designation in <i>Ordering Information</i> from the MAX20090ATP/VY+	28
3	4/18	Removed future product designation in <i>Ordering Information</i> from the MAX20090AUP/V+	28
4	1/19	Added MAX20090B to data sheet title, updated <i>Simplified Typical Operating Circuit, Simplified Schematic, Electrical Characteristics, Typical Operating Characteristics, Pin Configurations, Block Diagram, Detailed Description, Applications Information, Typical Operating Circuits, and Ordering Information</i>	1–29
5	5/19	Added MAX20090BATP/V+ to <i>Ordering Information</i>	28
6	4/20	Updated <i>Typical Operating Characteristics</i> and <i>Detailed Description</i>	8, 19, 20
7	6/20	Updated <i>Detailed Description</i> and <i>Ordering Information</i>	14, 27
8	1/21	Updated <i>Pin Configurations</i>	9
