General Description
The MAX44242 evaluation kit (EV kit) provides a proven design to evaluate the MAX44242 low-input bias current, low-noise operational amplifier (op amp) in an 8-pin µMAX® package. The EV kit circuit is preconfigured as noninverting amplifiers, but can be adapted to other topologies by changing a few components. The component pads accommodate 0805 packages, making them easy to solder and replace. The EV kit comes with a MAX44242AUA+ installed.

Features and Benefits
● Accommodates Multiple Op-Amp Configurations
● Rail-to-Rail Outputs
● Accommodates Easy-to-Use 0805 Components
● 2.7V to 20V Single Supply or ±1.35V to ±10V Dual Supplies
● Proven PCB Layout
● Fully Assembled and Tested

Quick Start
Required Equipment
● MAX44242 EV kit
● +5V, 10mA DC power supply (PS1)
● Two precision voltage sources
● Two digital multimeters (DMMs)

Procedure
The EV kit is fully assembled and tested. Follow the steps below to verify board operation:
1) Verify that the jumpers are in their default position, as shown in Table 1.
2) Connect the positive terminal of the +5V supply to VDD and the negative terminal to GND and VSS.
3) Connect the positive terminal of the precision voltage source to INAP. Connect the negative terminal of the precision voltage source to GND.
4) Connect INAM to GND.
5) Connect the positive terminal of the second precision voltage source to the INBP pad. Connect the negative terminal of the precision voltage source to GND.
6) Connect INBM to GND.
7) Connect the DMMs to monitor the voltages on OUTA and OUTB. With the 10kΩ feedback resistors and 1kΩ series resistors, the gain of each noninverting amplifier is +11.
8) Turn on the +5V power supply.
9) Apply 100mV from the precision voltage sources. Observe the output at OUTA and OUTB on the DMMs. Both should read approximately +1.1V.
10) Apply 400mV from the precision voltage sources. Both OUTA and OUTB should read approximately +4.4V.

Ordering Information appears at end of data sheet.

Detailed Description of Hardware

The MAX44242 EV kit provides a proven layout for the MAX44242 low input bias current, low-noise dual op amp. The IC is a single-supply dual op amp whose primary application is operating in the noninverting configuration; however, the IC can operate with a dual supply as long as the voltage across the VDD and GND pins of the IC do not exceed the absolute maximum ratings. When operating with a single supply, short VSS to GND.

Op-Amp Configurations

The IC is a single-supply dual op amp ideal for differential sensing, noninverting amplification, buffering, and filtering. A few common configurations are shown in the next few sections.

The following sections explain how to configure one of the device’s op amps (op-amp A). To configure the device’s second op amp (op-amp B), the same equations can be used after modifying the component reference designators. For op-amp B, the equations should be modified by adding 10 to the number portion of the reference designators (e.g., for the noninverting configuration, equation R1 becomes R11 and R5 becomes R15).

Noninverting Configuration

The EV kit comes preconfigured as a noninverting amplifier. The gain is set by the ratio of R5 and R1. The EV kit comes preconfigured for a gain of +11. The output voltage for the noninverting configuration is given by the equation below:

\[ V_{OUTA} = \left(1 + \frac{R5}{R1}\right) V_{INAP} \]
**Differential Amplifier**
To configure the EV kit as a differential amplifier, replace R1–R3, and R5 with appropriate resistors. When $R1 = R2$ and $R3 = R5$, the CMRR of the differential amplifier is determined by the matching of the resistor ratios $R1/R2$ and $R3/R5$.

\[
V_{\text{OUTA}} = \text{GAIN} \left( V_{\text{INAP}} - V_{\text{INAM}} \right)
\]

where:

\[
\text{GAIN} = \frac{R5}{R1} = \frac{R3}{R2}
\]

**Sallen-Key Filter Configuration**
The Sallen-Key filter topology is ideal for filtering sensor signals with a second-order filter and acting as a buffer. Schematic complexity is reduced by combining the filter and buffer operations. The EV kit can be configured in a Sallen-Key topology by replacing and populating a few components. The Sallen-Key topology is typically configured as a unity-gain buffer, which can be done by replacing R1 and R5 with 0Ω resistors and short JU2. The noninverting signal is applied to the INAP test point with JU2 short and short pins 1-2 on JU3 or do the same on the INBP pad similarly. The filter component pads are R2–R4, and R8, where some have to be populated with resistors and others with capacitors.

**Lowpass Sallen-Key Filter**
To configure the Sallen-Key as a lowpass filter, populate the R2 and R8 pads with resistors, and populate the R3 and R4 pads with capacitors. The corner frequency and Q are then given by:

\[
f_C = \frac{1}{2\pi \sqrt{R2 R8 C3 C4}}
\]

\[
Q = \sqrt{\frac{R2 R8 C3 C4}{C3(R2 + R8)}}
\]

**Highpass Sallen-Key Filter**
To configure the Sallen-Key as a highpass filter, populate the R3 and R4 pads with resistors and populate the R2 and R8 pads with capacitors. The corner frequency and Q are then given by:

\[
f_C = \frac{1}{2\pi \sqrt{R3 R4 C2 C8}}
\]

\[
Q = \sqrt{\frac{R3 R4 C2 C8}{R4(C2 + C8)}}
\]

**Transimpedance Application**
To configure op-amp U1-A as a transimpedance amplifier (TIA), replace R1 with a 0Ω resistor and install a shunt on jumper JU1 and shunt on pins 2-3 on jumper JU3. The output voltage of the TIA is the input current multiplied by the feedback resistor:

\[
V_{\text{OUT}} = \left( I_{\text{IN}} + I_{\text{BIAS}} \right) \times R4 + V_{\text{OS}}
\]

where R4 is installed as a 10kΩ resistor, $I_{\text{IN}}$ is defined as the input current source applied at the INAM pad, $I_{\text{BIAS}}$ is the input bias current, and $V_{\text{OS}}$ is the input offset voltage of the op amp. Use capacitor C8 (and C7, if applicable) to stabilize the op amp by rolling off high-frequency gain due to a large cable capacitance. Similarly, we can configure op-amp U1-B for transimpedance application.

**Capacitive Loads**
Some applications require driving large capacitive loads. To improve the stability of the amplifier, replace R6 (R16 for U1-B) with a suitable resistor value to improve amplifier phase margin. The R6/C9 (R16/C19 for U1-B) filter can also be used as an anti-alias filter, or to limit amplifier output noise by reducing its output bandwidth.
